LOS ANGELES SAN FRANCISCO

JULY 7, 1905

These are busy days in the deciduous orchards of San Joaquin Valley. Hundreds of tons of green deciduous fruits is the daily output.

CIRCULATION EXCEEDING 10,400

... COULSON'S SPECIAL MOULTING FEED ...

A FEATHER GROWING FEED

A specially prepared or properly balanced mixed feed containing the right component parts of materials for producing the rapid growth of feathers.

The term "molting" denotes the process of the birds shedding their old feathers ,and growing new plumage.

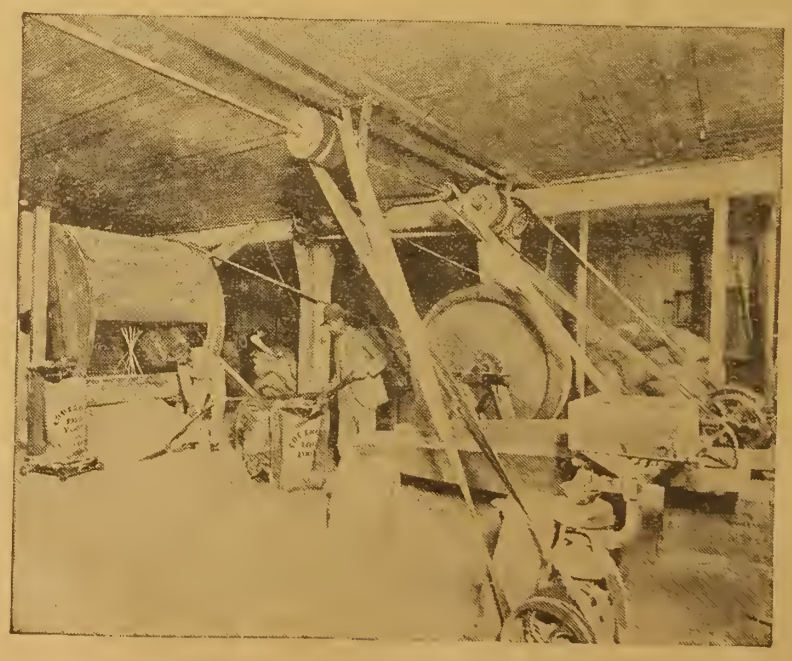
It is not necessary to starve the hens to make them molt, neither is it necessary to stop egg production. Hens fed with good feed and with good digestive capacity, can lay eggs and make feathers at the same time.

Keep hens for profit—intelligent feeding returns a profit. Feed a good balanced ration (Coulson's Egg Food) the year round so as to keep the fowls in good normal and healthy condition; then when the molting season comes and you want your fowls to molt, and get through molting before winter sets in, just start feeding them COULSON'S SPECIAL MOLTING FEED, and the fowls will soon be getting a beautiful glossy plumage (due to articles in the feed) and will get their new feathers in short order; for in this Special Molting Feed they get the material needed for feather production.

Knowledge is power, and the knowledge needed now by poultrymen is to know just what foods contain the most of certain kinds of nutriments, and will produce the rapid growth of feathers and also keep the bodily health of the fowls. This is why it pays to feed Coulson's Special Molting Feed during the molting season.

Young healthy fowls fed on the right kind of feed will complete their molt in sixty days; older fowls will take longer. Birds not properly fed during the year will be weak during the molting season; they lack vitality, and will molt very slow, probably taking six or more months to get their new growth of plumage, and quite a number of the weaker birds die from the strain of molting or from exposure.

Loading Cars with Coulson's Food for Laying Hens



Interior Scene of Coulson Co. Manufactory

Young birds will molt and grow new plumage at expense of health; old fowls will keep up their bodily needs, and go bare unless they are furnished the proper food to make the feathers grow.

The molt is a strain on the vitality of any fowl, for besides keeping up the heat ,and wear and tear of the body, the fowl must produce and grow new feathers; consequently the fowls should be fed a good rich food containing the right component parts of ingredients that will make feathers, and unless fowls are kept in good healthy condition, and fed the right food, many fowls will die during the molting season.

When fowls have been fed the year around one meal a day of Coulson's Egg Food so that they are in fine health at the beginning of the molt, if they are fed then for two months on Coulson's Special Molting Food, the growth of new plumage will be rapid, the new feathers appearing gradually as the old feathers drop off; and the bird may never appear worse than a little rought coated, and the eggs production will average about one in three days. Some birds even doing better, according to their digestive capacity.

Any one keeping fowls will surely be pleased to get eggs in fall and winter when eggs are bringing the highest prices. For this reason one should assist the fowls during the molting season, by feeding them Coulson's Special Molting Feed, so that the fowls will get through the molt before the winter weather sets in. The fancier also desires his fowls to complete their molt early so they will be in exhibiting condition for the poultry shows.

Fowls fed on Coulson's Special Molting Feed will have a beautiful bright, glossy plumage (a condition of perfect health), and will be pleasing to the eye, so that the owners will be proud of their birds. This feed supplies the fowls with the minerals and protein substance etc., needed for the growth, so that fowls can complete their molt and begin laying before winter.

CALIFORNIA CULTIVATOR

A WEEKLY JOURNAL DEVOTED TO AGRICULTURE IN ALL ITS BRANCHES.

Vol. XXV—No. 1 LOS ANGELES, CAL., FRIDAY, JULY 7, 1905 Subscription $1 a Year

Is Deep Orchard Cultivation Beneficial

Does it pay to plow so deeply as to cut roots? Are the trees injured if some roots are cut?

An investigation of the average orchard of California reveals the fact that it is not ordinarily up to the condition which most orchards are, have received attention from newspapers as model orchards. In other words, the average orchard if far below the condition which prevail in the orchard which is planted for profit.

It is far easier to take a model orchard and show the good points wherein it has secured its degree of success than to take one which is not a model and bring from it lessons which may aid in raising the general average. But mistakes to be avoided are sometimes just as desirable to learn about as are the successful methods. Therefore. it is possible some little profit many be secured by inquiring of those orchards that are only average or below the average and learning wherein they may be raised to a higher state of productivity and besides place upon the market a higher grade of fruit than is now done.

While talking with the managers of one of the orange packing houses of Southern California recently, the remark was made to us that in a fairly good year, that is a year in which conditions favored production of fine fruit, ten per cent was a high average of the fruit which would pass as fancy or extra fancy. A little more would go as extra choice, but the great majority would be classed under simply choice.

Now, while it is well know that picking, packing, business management, freight and practically all other expenses are just as great on a low grade fruit as a high grade and that the draft upon the soil is just as great to produce a cull as it is to produce a fancy, it appeals to us as a most vital question—how can the orchards be put into the condition which will raise the percentage of the higher grades?

It goes without saying that many individual trees will never, under any method of cultivation, produce a first class fruit. The orchardist should have intelligence and grit enough to learn which trees those are and uproot them without allowing them to take further nourishment from the soil and further place on the high priced land which usually prevails in California. Of course, some of these trees may be stocky, thrifty, in general condition, but of a variety which is inferior. Of course, such roots and stalks may be saved by rebudding and removing the old top entirely, but discussion of that side of the question is not the purpose of this article, so much as to determine whether in the soil, mechanically or chemically, there is a condition which should be corrected to greatly increase the percentage of fine fruit. Observation quickly determines that that is a greater factor than the question of varieties for many orchards have been rebudded where there has been a mistake in the purchasing of the root to the extent that nearly all orchards are now fairly true to name.

Rye Grass Hay on San Joaquin reclaimed lands

Gathering Pole Beans on Delta Lands near Stockton

* * *

Mechanical Condition. — While it may be a question which many will dispute, we believe there are vastly more orchards in unthrifty condition from lack of attention to the mechanical condition of the soil than there are to the lack of chemical fertilizer. This is not to be meant to be any reflection whatever upon commercial fertilizer for we believe they have a vast influence for good in the hands of the intelligent orchardist and later will be given more attention than in this paragraph.

Almost invariably the unthrifty looking orchard will be found to have an artificial hard-pan, will be found to have its roots altogether too close to the surface, will be found to have been treated to shallow cultivation for a period of years, as a rule seldon plowed, and likewise generally treated to frequent irrigations of short duration. Generally, the absence of weeds in this class of orchards is noticeable. That is, there has been clean surface cultivation, the orchard looks well cultivated and all surface mulch is fairly well fined, and very often the entire soil surface looks as if sandpapered. Therefore, we believe the mechanical condition depends more upon the treatment of the deeper soils than of the surface soil. Of course, it goes without saying, as has been spoken of in this paper many times, that following irrigation there must be early filling in of the wet furrow, to be followed by a system of cultivation which will save all the moisture possible.

Now, regarding the use of this surface soil, we are perfectly aware that Mr. J. W. Mills, of the Pomona Experiment station, has shown in these columns the great advantage of utilizing as much as possible this soil because of the heat of the sun an dthe action of the heat of the sun and the action greater proportion the food elements in the upper layers of the soil. But, regardless of the amount of root cutting which may be done by deep culture, we believe the roots will naturally soon fill any surface soil which may be kept in good tilth so that such fertility as is not carried down to the roots in the lower strata will soon be sought for by the little rootlets reaching up for it. Therefore, without combating his theory of the greater fertility of the upper stratum, we believe there is a vast storehouse of fertility below that will never be reached by the rootlets of the tree unless they are encouraged and even forced to seek those lower lvels.

* * *

An Experience.—The writer well recalls his experience in orcharding where too deep plowings every year were given, that is, deep surface plowings, not with subsoilers, but say ten inches at least, possibly twelve inches. In doing so, the roots of the trees, which were Washington navel orange trees budded on "sour" roots, which have a reputation for one of the most fibrous surface feeding systems of roots, and these were thrown out on the surface in great quantities. This was not true one year only, but every year, and, we recall, our neighbors who were not believers in the deep plowing system, would stand with expressions of actual pain on their faces and regret that the foolkiller was not present to save these orange trees. However, while that was ten years ago, these same orange trees today

POISONED STRAWBERRIES.

Along the line which Mr. Isaac spoke in his article last week, of the fake report of poisoning of eaters of strawberries from the Paris green, we note in the Sacramento Union reports from Florin which show that diligent inquiry has been made by interested parties regarding these reports, especially among the patches of the Japanese gardeners, and not only has there been found no ground for such talk but there has been found no reason why any Paris green spraying is ever used on strawberries.

The account says: "So far as known no predaceous or injurious insects have ever infested the strawberry vines in this vicinity and the conclusion reached by every one to whom the subject was mentioned was that the person who originated the statement was romancing. Should that report be false it is no more than just that the name of the person so reporting should be exposed and the indignation of an aroused community be wrought upon him."

REFRIGERATION OF PEACHES.

Readers will recall the recent accounts of the Cultivator of the experiments of G. Harold Powell, special field agent of the Department, with orange shipments from Southern California under special refrigeration. We announced at the time of the last article that Mr. Powell left the citrus experiments for the same line of work with deciduous fruit passing through Sacramento. At last reports ten carloads of peaches had been shipped from Newcastle to test his method of work. Of course, one of the principal points which Mr. Powell is determining is as to whether peaches may not be allowed to ripen on the tree and become sweeter, then placed on the market so as to reach there with less decay than has been the result in the past with much greener fruit. As was the case with oranges and prior to that with apples in the East, Mr. Powell recommends thorough ripeness of the fruit on the tree, careful handling and quick cooling from the temperature at which the fruit is at picking to 38 to 40 degrees and allowed to stay there until ready for delivery to the eastern purchaser.

From an interview in the Union, we note that W. A. Beard, secretary of the Sacramento Development Association, notes that, as was the case with the experiments in Southern California, "The present experiments will not be of a commercial nature, and Mr. Powell is careful to encourage no expectation of greater returns from shipments under his direction. The object is to determine whether the principal applies to California fruit, and if it does, commercial experiments will follow. The fruit shipped will be sold after the inspection.

"Newcastle is regarded as an especially favorable point because of the importance of the fresh fruit shipping business there. A number of growers are interested, and ten cars will be shipped. Two refrigerator cars will be sidetracked and used as cooling rooms.

"The experiments will be confined principally, perhaps wholly, to peaches for the present. Other fruits may be taken up later, and if the results justify and if the fruit growers evince an interest, the work may be extended later.

"The importance of this work to the fruit shipping business of California cannot be over estimated. Perfect refrigeration will overcome one of the principal drawbacks of the distance to market. At the present time California peaches intended for the Eastern markets are necessarily picked green. If the process of ripening can be arrested by perfect refrigeration Eastern consumers will be able to secure California peaches that are the real thing."

GEORGIA PEACH CROP.

There has been a material shrinkage in the peach output of Georgia this year, the Chicago Packer making the statement from a correspondent in the field that the crop will not be more than 35 or 40 per cent of last year's crop.

The Packer says. "Elbertas will begin to move between the 8th and 10th of July. There have been some few crops sold in lump, the buyer figuring they would cost $1 per crate f. o. b., while the grower figures on about $1.25. However, it is doubtful if there will be any money in them at $1 f. o. b., as it looks as if the whole State of Georgia will ship about the same time, the north and the south."

"SHORTS."

The Department of Agriculture of Canada is after the berry and small fruit growers who packed their fruit in short packages and is enforcing the law recently passed respecting the packing and sale of certain commodities, which reads that every box of berries or currants offered for sale shall be plainly marked on the side of the box, in black letters at least half an inch square, with the word "short" unless it contains, when level full, as nearly exact as practicable at least four-fifths or two-fifths of a quart.

ASPARAGUS.

Asparagus growers have had a hard season to contend with in the fact that the weather has been so cool that there has not been strong growth of that luscious vegetable. The season is now practically over, nearly all growers in the San Joaquin country having stopped cutting.

The Cultivator representative who is interviewing the farmers in Sonoma county, at this time about Santa Rosa, writes that the different growers with whom he has talked say that the prospects for large crops generally are good. Fruit is now showing better growth and the weather is much more favorable than earlier in the season. The section in which he is, especially about Healdsburg, Windsor, Fulton and Santa Rosa is largely wine grape country. Sulphuring is practiced very generally. The crop outlook is most favorable and should vary, from present indications, from three to eight tons per acre, owing to soil and other conditions. The growers have been assured that the price will not be under $15.

GOOD HOP PRICES.

In the canvass of various fruit sections, the Sacramento Union is finding a serious condition confronting the hop growers as to the total output, also determination on the part of the growers to stick to all the traffic will bear in the matter of prices. We sincerely hope the growers will consider their own interests enough to not get panicky and be willing to take any offering which the buyers may make. A great many of the growers are asserting that they will insist on the 30 cent price and stick until they get it, but already it has been found that some of these got "cold feet" after a smooth talk by the buyers. It is rumored that one buyer is attempting to induce Oregon growers to ship their hops to London and at an advance of 20 cents a pound. No reference is made to any such offer being made to California growers.

Regarding the condition of the market, the paper says:

Coast dealers are all back at their "old stands" ready for business. Generally at this time of the year they are on fishing or other vacations. Many of them have orders around 20 and 21 cents. They probably think soon will be a good time to pick up hops cheap before the advance gets fairly started.

As far as I can see the only thing the hop grower can safely do is to "lie low and say nuffin."

The chances are more in favor of a small yield than a large one. Nothing can definitely be known for six weeks yet.

Speaking of the situation, one grower says:

"Is it not time that we growers of California got together and talked over the proposition of a California Hop Growers' Association? Is there not brains enough among us hop growers to run an up-to-date business combination?"

CURE FOR PEAR BLIGHT.

A correspondent in the Farm and Ranch gives the following cure for pear blight which, if it works, is too simple and economical to be much of an obstacle in the way of saving the pear orchards of California. To be sure, the remedy was tried only on a few trees about the yard, therefore we warn our people that, as more than one swallow is necessary for a summer, this remedy may be taken with some grains of "salt." However, it is so simple that we advise a trial of it.

Regarding this remedy, the correspondent says:

"I had a fine young Bartlett tree standing in my yard; it blighted so badly one spring I cut away the entire top and burned it There was nothing left of the tree but a stub about twenty inches high. The same year it threw out new branches and made a wonderful growth. The next spring it blighted again. The top was cut away and burned as before.

Soon after this I noticed a remedy for pear blight; it was to put salt around the roots of the tree; this I tested at once, first pulling away the soil from the roots of the tree. Then I poured about one pound of coarse salt close around the tree raked the soil back and the job was finished."

This same remedy was then tried upon other trees by the same correspondent, every one of which has failed to show a particle of blight since the application of the remedy.

FRUIT TRAYS FOR SALE

BEEKEEPING FOR BEGINNERS.

I have frequently referred during the past few weeks to the bright prospects the present season for beekeeping in our State. There are two requisites, in California, for a good honey flow; we must have abundant rains during the winter season and warm weather during the time that the flowers are in bloom. The present season is ideal from the first standpoint; but for most of the season, so far, the weather has been too cold for either nectar secretion or for the bees to work well. I am now on the Sacramento river and I find that here, as also in the South, the unusually cool weather has worked to interfere with the storing of honey. In the past few days the weather has warmed up somewhat and the bees seem to be doing better. As I have before remarked, honey should never be extracted until it is fully ripe. This will not occur until it is at least partially capped over. We cannot too strongly urge that no one ever extracts unripe honey. Nothing will do more to injure the individual beekeeper or more to injure the industry than putting unripe honey on the market. It is quite otherwise with comb honey. While extracted honey is better left long in the hive, comb honey is better if removed early. If we wish our comb honey to be the whitest the supers containing the sections should be removed as soon as the honey is capped. If the bees use the combs as a highway for travel the comb will become somewhat stained and will not present that immaculate appearance which is so attractive in first-class comb honey. In case comb honey is removed from the hive, it is important to see to it that it is not injured by the bee moth. I have before remarked that the good beekeeper will have little to fear from this insect. This is certainly true in regard to the brood chamber and for the most part is true regarding every part of the hive, and the honey as well. It is true, however, that the moth will sometimes lay eggs upon the comb honey if left exposed and thus this product will receive serious injury. It is wise, therefore, to never suffer the honey to remain in exposed places. It is well to put it in rooms or boxes so tight that the bee moth cannot gain entrance and deposit her eggs on the comb. In case this is impossible, as is often true, it is always well to subject the comb honey soon after its removal from the hive to sulphur fumes. These should be strong enough to surely kill all larvae that might be at work. Even such a veteran, capable and experienced beekeeper as Doolittle recommends this fumigation preliminary to the shipment of comb honey.

As with all products of the farm, it is wisest to market and ship our honey as early as may be after the harvest is over. There are several reasons for this. First, it is good to have our money in our pocket; second, an early market is quite as likely to be the best, though this is not always the case; third, it is safest to ship, especially comb honey, before the cold weather sets in. Cold makes the comb brittle and thus the sections are more liable to injury.

* * *

BEEKEEPING IN NORTHERN CALIFORNIA.

It was my pleasure a few days since to visit my friend, Mr. Thomas J. Stevenson, on the Sacramento river, at Courtland, who is not only an extensive dairyman, but also an extensive grower of alfalfa. He also has a large and neatly kept apiary. Indeed, I knew his father as a successful beekeeper in the same place along in the sixties. Mr. Stevenson tells me that he gets a pretty fair crop of honey each season and, except that the weather is cold, he always looks for a large crop. I noticed the other day that on many of the hives he already has two supers and in some of these the sections are entirely filled. This honey seems to come largely from alfalfa. We see then, why the crop is rarely a failure. The water plane to so near the surface that alfalfa is invariably a success and is always grown without irrigation. Here, then, the beekeeper is independent of the rain and can usually count on a fair return for his labor and pains. It is a curious fact that alfalfa does not always seem to furnish nectar. It is true, though, that in the San Joaquin and Sacramento valleys, there is rarely a failure. Of course here, as elsewhere, if the weather is very cold, we cannot expect a large honey crop. A prolonged cold spell, however, in these valleys, is not to be expected. I believe that there is rich opportunity in many of the alfalfa regions along the Sacramento, where no bees are now kept for new apiaries. It was my privilege only yesterday to visit the wonderful Lisbon reclamation district, where I saw the finest alfalfa fields that I ever looked upon. Yet so far as I saw, there are no bees at all in this district. It would be better for the farmers if apairies were brought to these alfalfa fields. One of the chief sources of gain is in the seed from the alfalfa. There can be no question but what the seed will be much more abundant if bees are present in sufficient numbers to provide for ample pollination of the crop. Here, then, as in Nevada, Arizona, Colorado and Utah, the beekeeper and the general farmer will be mutually helpful to each other.

* * *

EN ROUTE FOR EUROPE.

We are already on our way to the other side of "the great pound." We passed, the other day, by the great orchards of Pajaro and Watsonville. I was surprised at the indifferent cultivation which I noticed in many of the apple orchards of that section. It illy comports with the splendid cultivation with which I am familiar in the citrus orchards of Southern California. Surely, with a fruit as valuable and important as is the apple in California, no grower can afford to neglect the best culture. Mr. Powell tells me that his father, in New York, has succeeded by use of cover crops and the best cultivation, to make his apple orchard an annual bearer. He has thus nearly doubled his profits. I suggest to our readers in the Pajaro region that they act in this matter and see if they cannot also duplicate Mr. Powell's experience.

* * *

We also stopped off in the famous Santa Clara Valley at San Jose and Palo Alto. Here, as I expected, the orchards show a high state of cultivation. It goes without saying that the best fruit can come only with deep and ample tillage. I believe in Northern California, as in the southern part of the State, one of the great reforms in orchard culture will come with the use of some suitable legume as a cover crop in the orchard.

* * *

PEAR BLIGHT.

I was exceedingly interested in covering the same ground through the famous Bartlett pear region of the Sacramento that I traversed last autumn. It will be remembered that I then noted that the pear blight very much in evidence. Nearly every orchard showed its fell presence, while many were suffering very seriously. Today, I noticed very much less. While it is possible that the cool spring may have had some part in the better condition of the orchards, yet I believe, that not a little comes from the fact of Prof. Waite's presence and influence among us. Prof Waite urges the utmost vigilance in pruning off diseased branches and in the careful use of disinfectants while pruning. I suppose that it was largely due to the urgent request and push of Mr. Ernest A. Gammon, of Courtland, that Prof. Waite was sent by the Department of Agriculture to this important work. As we should expect, Mr. Gammon has been most vigorous in following to the letter Prof. Waite's advice. I have seen no other orchard so entirely free from blight as is his. Mr. Gammon keeps a very active man constantly at work. This man has gone over the entire orchard sixteen times and over portions of it eighteen times during this present season. The entire cost of this has been less than $100, while if the work saves the orchard, it will mean thousands of dollars in the pocket of the owner. I wish all of the growers were as alive to their interests as is Mr. Gammon. This is a matter of tremendous importance to the industry of our State. It is not only imperative that this close pruning be followed by every grower for his own profit and interest, but equally important for the good of the industry as a whole. Every man who fails to stamp out this disease becomes a public enemy. Let us remember how the Fresno region was utterly robbed of its great pear orchards through neglect to battle vigorously with this pear blight. The value of the pear industry in the Sacramento valley reaches way up to big figures. It is bound to go, root and branch, except as orchardists go into the orchards fully armed with saw and pruning knife. With the requisite care and vigilance these magnificent orchards may be preserved and our State made richer by hundreds of thousands of dollars.

California Horticulturally

By John Isaac, Sacramento, Cal.

THE ANNUAL GRASSHOPPER SCARE.

The grasshopper scare is increasing in the northern counties, if the sensational press dispatches are to be believed. This is a pest that we may always expect to have with us so long as it can find suitable breeding grounds. It was infinitely worse in the past than it is of late years, and history informs us that as early as 1827 they ate up all the growing crops and from 1838 to 1840 they destroyed all the gardens about San Francisco and San Rafael. There are yearly recurring swarms all along the warm gravelly foothill sections of the State, as it is here that they find their ideal breeding grounds. But as the country becomes more extensively and more thoroughly cultivated these swarms become less and, while they now sometimes appear to be serious enough to those who have orchards or farms near their vicinity, they are nevertheless much fewer and less destructive than they were in the past. Another good thing about our California locust is that its depredations are limited to a few weeks duration early in the season. This season is long enough, but they are not so bad as the Rocky Mountain locust which continues to devastate the country in enormous swarms through the whole season. As soon as the California hopper acquires wings the worst of its work is over. It then spreads over a large area, and while it may do some damage, it is so widespread that its results are not so noticeable as when they are confined to a limited area. The best remedy for the pest so far is the bran, arsenic and molasses mixture, which has been found effective in the State for so many years. It will not exterminae them, but in the case of threatened vineyards or orchards, it will reduce their numbers and the consequent damage materially.

* * *

NEW HORTICULTURAL OFFICER.

Mr. E. O. Bremner, who has been acting as County Horticultural Commissioner of Sonoma county for some time past, has received the appointment as Assistant Inspector in the office of the State Horticultural Commissioner at San Francisco. This appointment has been made in accordance with the sentiments of the fruit growers as expressed at the last Convention, when it was decided that it was necessary to have more assistance at San Francisco to properly look out for their interests at that port. Mr. Bremner has made a good reputation as a skillful entomologist and as an efficient officer in his own county and will undoubtedly make a good record for himself in his new office.

* * *

THE NEW CODLING MOTH PARASITE AT WORK.

In all my statements in relation to the work of beneficial insects in these columns, I have attempted rather to understate than to over estimate their work. I have always found it safer to tell what they have done, rather than what they are going to do, as there is always a great deal of uncertainty as to how an introduced species will behave itself in its new home. This was my policy in regard to the Scutellista and it was not until I was fully convinced of its good work in our orchards that I claimed for it the credit which it now justly receives. There is now no doubt that it is the enemy of the black scale and, while there may be occasional outbreaks of this pest, it will never again be the destructive and costly enemy to our fruit growers that it has been in the past. I have so far refrained from claiming much for the new parasite of the codling moth, for it is a new insect here, our conditions are very different to those of its native land, and there are numerous contingencies to be met before it can be claimed to be successful. In confinement it is without doubt a very effectual enemy of the moth, but what it would prove in the open is yet somewhat uncertain. It is for these reasons, therefore, that I am more than pleased to quote the following from a private letter received concerning the work of this new parasite in the orchard. As this communication was in the nature of a confidential statement from one who is interested in the work of this parasite to another who is equally interested, and was never intended for publication, its statements may be accepted without question, and serves to indicate that we have at last secured what there is every reason to believe an effective check to one of the worst orchard pests in our State.

"Yesterday went over to Novato, to the property of the Novato Land Company, in response to a statement that the Ephilates were there by hundreds. The place has 11,500 acres in it, the old DeLong apple orchard, and I was very much surprised and more than pleased to find the parasite flying about in large numbers, found them on my hands, caught them in my net, and had the pleasure of having the foreman tell me that this is the first season in many years that the orchard was nearly so free from worms. They claim that there is over 50 per cent improvement over past years. The fruit looked well and there are very few wormy apples. This is certainly very encouraging, and as I saw it myself I know that it is so."

* * *

PEAR BLIGHT LESS VIRULENT.

Reports from the pear section of the northern counties are rather encouraging so far this season, and indicate that the disease is not so virulent as it was a year ago. In many of the orchards along the Sacramento river, where it was so bad last year, there is very little indication of it this season, although in others it has shown up in full force, and in all is certainly bad enough. So far, this disease has not been nearly so bad in the northern counties as it was in Kings, Tulare and Fresno counties a few years back, and growers are hoping that it has "run its course" and will not be so troublesome in this section as had been feared. There is yet ample time, however, for it to manifest its presence on a wider scale, but as yet there is every reason to believe that it will not be so bad as it was last season.

The young man who wrote and asked his girl to accept a "bucket" of flowers became a little pale when she said she wooden ware it.

ANAHEIM DISEASE INCURABLE.

Professor Bioletti, recently returned from South Africa and now at the head of the Viticultural Department of the State University, announces that he fears that the Anaheim disease, which is proving to be so deadly in many vineyards of both north and south, is incurable. In addition, Professor Bioletti has been investigating the work of the Adoxio-Vitis, a beetle fly which is supposed to cause the grape to fall to the ground. The Adoxio Vitis is also supposed to be responsible for the flecked condition of the grape known as "sunburn." Professor Bioletti has made a study of both of these diseases and finds that the beetle is responsible for the falling of the berries, but not for the sunburn, and it will be necessary to look for some other cause for the sunburn if it is expected to eradicate it from California orchards.

CURL LEAF.

Editor Cultivator:—I am much interested in discussion of insecticide and fungicides in the Cultivator and ask for information regarding preventing the trouble of curl leaf and what I believe to be the shot-hole fungus on peach trees. The leaves wilt and die soon after coming out in the spring, especially on the lower branches.—R. R. B., Hanford.

Any one desiring information regarding curl-leaf should write the Department for "Peach Leaf Curl," a report by Newton B. Pierce, published by the Department of Agriculture, Washington, D. C. Treatment for the trouble is with the Bordeaux or sulphur lime and salt spray, applied in the winter when the trees are dormant. The description which you give, however, of leaves falling soon after appearing hardly applies to the peach leaf curl. The name of the disease is descriptive of the trouble, for the leaves draw and pucker out of all shape and give a regular curl or distorted appearance which may not be yellow, more likely is green. However, the washes which we have recommended, description for the making of which appeared in a recent number of the Cultivator, are good preventives for any fungus disease.

GOOD ROADS.

In talking to a farmer recently after driving to the city of Los Angeles from an outlying section with a load of produce, we are convinced more than ever that financial advancement cannot come to farmers of this State faster than by working for better roadways over which to carry the produce of the ranches to market. The farmer in question remarked that in going to market with his load of produce he met generally hundreds of teams, for the road was one of the most traveled into the city. His trip occupied twice the time it should have taken, because of the great chuck holes which filled this well traveled thoroughfare. With light driving rig or even with a light load, the loss from such roads is not so noticeable as where the farmer attempts to move his heavier crops. But, as it was, the whipping from side to side of the pole of the wagon even endangered the legs of his horses, and caused serious wear and tear upon harness, wagon and team. He ended his account of the trip in and the incidents connected with it with the question, "When will Californians wake up to the fact that the cost of transporting farm produce to market must be materially reduced if we are to compete with other sections of the world in marketing our produce. It is almost impossible to conceive the difference in cost between transporting a load over a smooth hard road of even grade and that of the ordinary chuck-hole, dust, boulder combination."

We presume it will be many years before this farmers' question will be answered.

One of the leading and successful real estate men of the Middle West, A. P. Tone Wilson, of Topeka, Kansas, is now advertising in something over 2500 different papers and magazines and has connections with over 2000 agents and branch offices. He is a real estate specialist and is strongly recommended by the daily and weekly papers of his home city. His advertisement appears in this paper.

New York state, especially the western portion, will have a full peach crop this season.

CITRUS FRUITS

By C. A. Day. Pasadena

AERATION OF SOIL.

In other articles I have emphasized the importance of the presence of water in the soil, but the presence of an ample amount of air in the soil is as indispensable to the life of upland plants as is that of water. When the soil is flooded and the pores fiill with water for any great length of time, the upland plants will sicken and die, and this too, when they are in full leaf and are abundantly supplied with food and warmth. The cause of this is that the water excludes the air from the soil and prevents the root-breathing of the plants. Water plants, like the pond lily, whose roots are continually in soil under water, are provided with a system of air cells in the plant and its roots that furnish the roots with the needed amount of air. All plants require air for root breathing.

Plants that form water roots secure their supply of oxygen from the water, as all water contains a certain amount of air. Water is more easily penetrated by air than the soil and where the pores of the soil are water clogged there is practically no ventilation and the soil water does not absorb the air.

The oxygen of the soil air is withdrawn for use in the chemical action taking place and where there are leguminous plants the nitrogen is used by the micro-organisms to replace the oxygen and nitrogen so used. There must be a free ventilation of the soil to admit fresh supplies of these elements.

Air is also indispensable in the work of nitrification or the change of the nitrogen of the soil into nitrates in order to become available for the use of the plant or tree. The micro-organisms which form the nitrates require the presence of air in the soil. Not only must it be present in the soil but there must be a free circulation in order to furnish fresh supplies of oxygen for the use of the micro-organisms of ferment. Carbon dioxide is also produced in the soil and the oxygen and carbon used must be furnished by the soil air.

To influence soil ventilation the soil should be porous and the surplus water should readily pass down into the subsoil, the air following the water and thoroughly aerating the soil in which are located the root system of the plant. With certain soils over irrigation will fill the pores of the surface soil and exclude for a time the air, with injury to the tree. While we have advised heavy irrigation on ordinary soils, there are cases where the soil can be over-saturated with water to the injury of the tree There are two ways in which the air can be excluded from the soil, first by excess of water that shuts out the air; second, by the forming of a hard soil stratum near the surface that partially or wholly excludes the air and prevents soil ventilation.

There are three ways in which to aerate the soil, by deep tillage, the presence in the soil of a good supply of humus and vegetable fiber, and the use of deep-rooted, green manuring plants that penetrate the sub-soil, which by decaying leave air passages. Earth worms are also a means of aerating the lower depths. Deep tillage, the supplying of humus and vegetable matter and the growing of green soiling crops will acrate the soil and in many cases will produce a wonderful change in the condition of the trees.

* * *

Soil Temperature.—"There is no physiological fact more evident than the extreme importance of maintaining the right temperature surroundings for living forms of all kinds." The work of nitrification is accomplished by the micro-organisms that change the humus of the soil into available form for the use of plants. These micro-organisms of ferment and putrification are a lower order of plant life and not only require water and air but will not be effective only when the temperature of the soil is raised to a certain degree. The lowest soil temperature, according to Ebermayer, at which the processes of growth are started in most cultivated crops, is from 45 to 48 degrees F., but the mixiumum results are attained only after the soil has reached a temperature of 68 to 70 degrees. With a low temperature it will require several days to accomplish the same results in furnishing available nitrogen where, with a high temperature, the same result would be accomplished in a sigle day. King, in his work on soil says: "One of the chief functions of soil water is to take into solution from the soil constituents, substances which, for the most part, dissolve, under the most favorable conditions, very slowly. Now, raising the temperature of the soil grains weakens the attractive force which holds the plant food locked in the solid state, while at the same time it makes the diffusion of the dissolved materials, away from the seat of action, more rapid," and unless the dissolved materials are removed as soon as formed, they, by their reaction against the force of the soil grains, tend to prevent further action from taking place. It is not only important that there should be a rapid diffusion of the dissolved food away from the places where it is being formed, through action of soil water, but it is even more important that this process should be carried forward in the soil air.

Heat is the source of energy in plant growth. Increase of heat stimulates growth of plant life. Water absorbs heat very much slower than soil grains and a soil saturated with water warms but slowly. The evaporation of water from soil surface rapidly lowers the temperature of the soil, for it takes 966.6 heat units to evaporate a pound of water and this heat by the evaporation is lost to the soil, therefore cultivation which prevents the evaporation of water increases the temperature of the soil. The influence of heat in the growth of wood and foliage in the citrus orchard is evident in midsummer and early fall. While the young orange tree will begin making wood in the month of March, the bearing orange tree does not make wood until July or until the soil temperature has increased to a degree that stimulates the micro-organisms to furnish a good supply of available nitrogen. When once the temperature of the soil is raised to the proper degree of heat, it retains the stored heat into the fall months continuing the growth of wood and the storing up of the reserve material for the bud and blossom of the next spring. All nitrogenous elements artificially supplied to the soil should be in available form at the beginning of the principal season of wood growth. It is sometimes important to reduce the heat in the soil, as for instance, during the late fall and winter season, when, with an open, warm winter, the orange crop is hastened to maturity, causing a severe dropping of the fruit. By observation I am inclined to believe that orange orchards during the past winter that had a covering of weeds or peas held their friut much longer with less dropping than where the orchards were cultivated and kept clean from all plant growth. It is probable that the shading of the ground from the rays of the sun lowered the temperature or, rather, prevented a rise in soil temperature.

THE TANGELO.

We referred last week to new creations in the line of citrus fruit as carried on in Florida by the U. S. Department of Agriculture, giving particular description of the citrange and its characteristics. Besides that fruit, the hybrids of tangerine and the better classes of seedling oranges have secured other desirable fruits.

The tangerine has also been used to cross with the pomelo which has given a citrus fruit neither an orange nor a pomelo, to which has been applied the name of tangelo.

The Tangelo.—Another group of desirable fruits has been secured by the crossing of the Dancey tangerine with the pomelo which gives a fruit neither pomelo or tangerine, not as sour nor as bitter as the pomelo, yet with more tartness and more of the appetizing quality for a breakfast food than the tangerine. This fruit is eaten from hand, more as a tangerine is, by separation of sections, dipped in sugar, rather than by scooping out the pulp, as is ordinarily done in eating a pomelo. It is claimed that this fruit will be a favorite with those who have found the pomelo too bitter or too sour for their taste.

New Tangerines.—There have also been a number of improved tangerines produced larger in size than the original tangerines and yet with its loose, easily removed rind and fewer seeds. One of these was secured by the crossing of the Dancey tangerine with the pollen of the Parson Brown orange. This is called the Trimble tangerine.

Another is the "Weshart tangerine," a delicious fruit of exceptionally fine appearance and flavor. Its large size, superior quality and earliness indicate that it will prove of great value for general cultivation in orange regions. In general it is smoother in surface and rather smaller than the Trimble tangerine, but is apparently superior in flavor."

"IT'S PENNY WISE"

Policy to set out a good tree, costing good money, and then let the sun burn the bark, or the rabbits gnaw it, when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructable. Write for free sample of the wrap. Yucca Mfg. Co., 450 Santa Fe avenue, Los Angeles.

VALENCIA LATE ORANGE TREES

Are getting scarce. We still have a few hundred first class trees that HAVE NOT BEEN CULLED OVER, and we are offering them cheap. Give us your order now. Also hade some Marsh's Seedless Grape Fruit, Dancy Tangerines, Navelencias, Lemons, etc. We can furnish these from our Glendora nursery, or other nurseries. Address

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

WOMAN ON THE FARM.

We have been reading what a large number of women have written about life on the farm and find therein some thoughts that are well worthy of a more extensive circulation. There is no question but too little of social life is in evidence in many rural communities; as one woman bluntly states it, "we attend one another's funerals, but have no time for other social functions." Organize a woman's club in every community for the betterment of the farm woman and her daughters. Select some subject from a current magazine for discussion, and thus obviate the tendency to gossip. This will give rise to expansion of home duties, as well as tending to broaden opinions upon the chief topics of the day. Keep plenty of good literature in the home. Where economy is necessary in purchasing magazines, families may club together and purchase a number to be read in turn, meeting once a month to discuss articles of general interest. Afternoon sewing circles could be made beneficial by a course of reading.

Bring up your children to respect farm life, and never let one word fall that shall give them cause to think there is anything degrading or uncultivated in being a farmer. Three-fourths of the occupants of farms, both men and women, need to fall in love with their farms and then set to work to clean them up. Though surrounded by the beauty and harmony of nature, many are blind and deaf to such environments. The farmer often has so little eye for the beautiful that the stable yard and ugly outbuildings form a veritable blot on the landscape instead of blending into the meadows and woodland beyond. Man has no right to make these "blots on the landscape." It is the duty of every one to at least replace as much of natural beauty as he destroys in denuding the earth to get a site for buildings, yards, etc. Put in plenty of trees, for shade and protection, as well as for ornament. Make the front yard fairly teem with herbaceous and shrubby flowering plants. Sow broadcast each season, or several times each year, seeds of flowering annuals, so that a constant change, and not monotony, is present. It is not necessary to go outside of our native flowers to supply these latter. They thrive better than the majority of pampered introductions, and aid to blend your little landscape into a part of that around you. Have flowers everywhere, taking advantage of every unoccupied spot. Looking at the things we love, watching them develop, and anticipating the fulfillment of their possibilities, lets the sunshine into the clouded brain and heart, brings a happy light into the eye, and a buoyancy to the step; therefore, "grow more flowers." The woman in the country in her nearness to nature has a beautiful opportunity, if she will cultivate her perceptive and receptive faculties . . . "The billowing fields of grain, the green of the circling forest, the drift of bloom, and the delight of perfect fruit hanging low on the boughs, all have wonderful messages for her alone, if she will take the time to see and learn them.

The spirit of beauty, like the kingdom of heaven, is within you, and you have only to become as little children and let the magic of Mother Nature charm the eye into seeing that sees not, and the ear into hearing that hears not, the beautiful sights and sounds of this fairy-like world of ours as the seasons come and go."

RESTING POT PLANTS.

House plants that have flowered through the winter should be given a rest and not allowed to go on blossoming. Summer is the season of inactivity for them and they should be started on it as soon as possible. Encourage them to recuperate; do not give rich soil or large amounts of water, for they encourage vigorous growth. The plants should remain as nearly dormant as is consistent with good health. Cut back well, prune into something like symmetrical form and keep watch of them as growth is made. Pinch back when it seems necessary to do so to secure good form. Act on the principle that you are trimming the twig from which the tree is to develop. Training and development should go on together. If you wait until a plant is developed it may be too late to train it into perfect form.

FOR DRY, HOT SOILS.

Portulacas are tender annuals which grow from six to eight inches high, and a bed of them makes a dazzling display of color in the bright sunshine. They should be sown during warm weather, as the seeds require a moderately high temperature for germination, and should be sown where the plants are to grow. The plants do best in a hot, rather dry ground, and the soil need not be rich. The flowers close in shadow but are open in sunshine, and are therefore peculiarly suited to our climate.

ATRIPLEX BREWERI.

The range of this excellent native "salt bush" seems to be quite limited, extending from a few miles above Santa Barbara to a point on the beach nearly opposite Los Angeles. The most southerly station, as far as we know, is at Ballona, or as it is now called, "Playa del Rey," where the writer found two plants on the shores of the lagoon. Though most useful for hedges, it makes a fodder plant worthy of trial; fowls of all kinds eat with avidity; one party who planted it for hedge finding it impossible to grow because the chickens ate off every leaf as soon as they appeared. As it grows wholly without care it may prove a profitable plant for poultry producers.

WORLD'S LARGEST TREE.

During the month of August, 1902, there was discovered in the Sierras east of Fresno, the biggest known tree in the world. It was later visited by John Muir, the naturalist, who reports that its circumference at the base is one hundred and nine feet, or a diameter of thirty-six and one-half feet. At four feet above the ground the circumference was ninety-seven feet. This tree is considerably larger than "General Sherman" and General Grant" the two which heretofore were the recognized monarchs of all "Big Trees."

HOME GROUNDS.

There is no work more entrancing than that of the arrangement of the home grounds, which comprises, in the broadest sense, extent of lawn, number and variety of trees, shrubs and other plants; location of flower beds, drives and paths; and the proper adjustment in the size, shape and color in the placing of the principal buildings. The country home has the advantage over the cramped grounds of the city, and has ample space for the proper disposition of all the above noted features.

Let your grounds be simple and restful rather than strain for bold effects, and an air of peace and quietness will pervade the whole and whether it be a cottage or a mansion, it will be a home in the fullest sense of the word, a fact readily noticed by the observant passer-by. A well known public man says: "We instinctively judge of a man's personality by the outward aspect of his home."

It is an unquestioned fact that the cultivation and care of a garden instils love of nature and has an uplifting and enobling influence on mankind. Go where you will, you will meet with the best reception in every way at such places where the greatest love is manifest for the beauties of nature. When the traveller comes upon a home where there is a roomy, well-planned, well-kept garden, he at once feels a desire to know the inmates personally, for he is certain to find there more or less of generosity, intelligence and refinement.

Children reared in homes where the parents are indifferent to the appearance of the home grounds, are indeed unfortunate, for they lose nearly all chance of acquiring that love of the beautiful which is so elevating, so enobling.

"One impulse from vernal wood
May teach you more of man,
Of moral evil and of good
Than all the sages can."

Those who, early in life, become imbued with this love of nature through home influences, carry it through life and it is a constant source of pleasure, not only to themselves, but to all who come in contact with them—an intense love of nature which marks them above their fellows. History proves that a taste for gardening has kept pace with the progress of civilization, and that it has always exerted a powerful influence upon the passions and feelings of mankind.

But it is not to the ornamental garden alone that the home gardener should apply all "odd moments;" the growing of fruits and vegetables is just as essential to the ideal life, just as uplifting in its influences, and certainly as profitable from a monetary standpoint. This part of the garden, more properly called the kitchen garden, should be so planted that it may furnish the family table with a succession of seasonable vegetables througout the year. The growth of a spring and summer crop may be sufficient for the snow-bound country east of the Rockies, but in California we may grow many "short period" crops, as lettuce and radishes, at any and all seasons. With the development of vegetables, such as the Crimson Winter Rhubarb, and others peculiarly suited to our winters, there is no reason why fresh vegetables should not be served to us during every month in the year.

A quiet home; vines of our own planting; a few books full of the inspiration of genius; a few friends worthy of being loved, and able to love us in turn; a hundred innocent pleasures that bring no pain or remorse; a devotion to the right that will never swerve; a simple religion empty of all bigotry, full of trust and hope and love—and to such a philosophy this world will give us all the joy it has.—David Swing.

BURBANK'S CRIMSON WINTER
RHUBARB

Plant 1,000 roots and you have laid the foundation for a good, steady income—an income that will average NET to you from $300 to $400 per acre, and in some instances even more has been realized.

PROGRESSIVE FARMERS are availing themselves of this unusual chance to secure a start in a crop of such sterling worth.

CRIMSON WINTER RHUBARB

Is very easy to grow, is a clean crop and a good shipper. Stems sent to the East during the winter bring 15c per lb., and more is wanted.

The industry is yet in its infancy, but at the present rate of growth will soon be one of our standard crops. As in any new industry, those who start early and right will realize the biggest profits.

A beginning can be made with 100 roots costing you $7.50, but for a right start you should plant at least 1,000 medium size roots delivered to your address for $50. $1.50 per dozen. I have free folder. Send for it.

General Agricultural Notes

IMPROVING BRITISH WHEAT.

From the Crop Reporter of June we note: During the past two years experiments likely to result in important practical results have been carried on by the National Association of British and Irish Millers, looking to the improvement of the quality of wheat grown in the United Kingdom. Ever since the importation of wheat into England has assumed such vast proportions it has been recognized that, in a general way, all the varieties of native-grown wheat are, in varying degrees, inferior in "bread-making strength" to wheat imported from several foreign countries; in other words, that the loaf of bread made from the flour of natve-grown wheat is perceptibly smaller in size than the loaf made from wheat imported from some foreign sources, although equal weights of flour, salt, yeast, etc., be used in all cases. Practical experience has taught that the sections from which wheats superior in this respect to the native varieties come are situated on the great Continental plains and include, among others, Kansas and the spring wheat belt of the United States, Manitoba and the Northwest Territories of Canada, southern Russia and Roumania, the great Hungarian Plain, and some sections of Argentina. It goes without saying that wheats from all these foreign sources vary greatly in strength, according to country, season, soil, climate, degree of maturity, etc. Their general superiority over British wheat, however, is demonstrated, among other things, by the price each commands in the English markets; for instance, the average prices of No. 1 Northern Manitoba, Hard Winter Kansas and Russian during the season of 1903-4 were, respectively, $1.06, $1 and $1 per bushel, while the average price of the best English wheat during the same season was no more than 88 cents per bushel. All imported wheats, it may be noted, are not characterized by this superiority in strength over the home-grown article. "The British Indian wheat, the Australian, and those derived from the Pacific slope of North America," says a well known English authority, "are no stronger than the ordinary run of English wheats."

Now, to stop the tide of influence against the British wheat in the market, the Association of Millers has been calling for investigations which are already looking to some good.

The experimental work already done by the Association epitomizes much of the remarkable advance that, within recent years, has been made in scientific agriculture. Experiments, though generally on a small scale, have been made in selection and in hybridization; the effects of fertilizers and of soil inoculation upon the strength of wheat have been observed; the relation of strength to spring sowing versus autumn sowing has been tested; and foreign seed wheats in considerable variety have been introduced both to try the effects of the English climate and soil upon them and to observe the results of crossing them upon the native wheats.

The pronouncements of the Association that are probably most interesting from the American point of view are those referring to soil inoculation and to the planting of seed wheat of foreign origin. Concerning the former, a member of the Homegrown Wheat Committee, speaking recently in a council meeting of the Association, said:

"You will probably have heard of the German method of supplying plants with nitrogenous food by fixing the nitrogen of the air, and of the American variation of the method, for which striking results are claimed. In co-operation with Rothamsted, we are applying both methods this year, that is to say, we have obtained bacteria both from Germany and America and have with them inoculated soil in the specified way to see whether there will be next year any difference in the yield of wheat and straw and whether the fixing of nitrogen in this method has any appreciable effect on the strength. We all know that wheat grown after clover is slightly stronger than wheat grown after roots, and this inoculation of the soil by bacteria which we are now varying is simply an application, in what is claimed to be an effective way, of the method employed by nature to fix nitrogen by the growth of clover.

"In other words, if this work be successful, we shall be simply carrying out a form of manuring. The work involved is little and the expense very small. If for no other reason we think the experiment well worth our attention, but, having regard to our experience as to the effect of manure and to the effect of growing wheat after clover as against growing it after roots, we do not think that the process will be of substantial importance to us."

The "effect of manure" above referred to, was stated by the committee to be "that long-continued applications of nitrogenous manures in heavy dressings do actually send up the total percentage of nitrogen and dry gluten, but the baking value of flour from wheat so treated is greatly deteriorated."

The introduction and testing of seed wheat from foreign countries has been carried out on an extensive scale. Hundreds of samples from various sources have been sown; the general result has been that, with a few exceptions, all foreign wheats degenerate when planted on English soil and behave very erratically, though sown under identical conditions. Kansas wheat so deteriorated that experiments with it have been abandoned. Of several hundred Russian samples, picked out by hand selection, all turned out utterly bad excepting four; the yield of wheat and straw was exceedingly poor and degeneration very prompt. Of the four exceptions, however, three are now being cultivated for the fourth year; one promises to furnish a wheat excellent both in yield and quality, another is maintaining a very superior quality admirably, and the third is conspicuous for standing English climatic conditions exceedingly well. Four of the principal varieties of Hungarian wheat were also grown last year, all of them characterized by great strength—two exceptionally so. Though this was their first year in England, they degenerated greatly and have been pronounced of no use. A peculiar feature was that the sort which was least strong when sown in Hungary degenerated the least when sown in England. Of all the foreign wheats experimented with, however, the most promising results seem to have been obtained from an improved Red Fife from the Government Experimental Station, Ottawa, Canada. This wheat is now in its third year in England, has been grown experimentally in several localities, shows great properties of strength, yields very abundantly, and possesses remarkable adaptability. It has already attracted unusual attention and this year is being grown in quantity in several parts of the country.

"These results," states a member of the Association, "seem of the highest importance, for our greatest concern is to find wheats which, even if they fail in other respects, maintain their strength in this country. If we can do this our ultimate success is certain. * * * We recognize that success will be determined by certain varieties, used as parents in breeding, retaining their strength under our conditions of soil and climate, and it is essential that this point should be tested to the uttermost. We can not wait for the final test, so are crossing together all the varieties of any promise, as far as strength goes, with a number of the best English varieties, and also with a few of the new ones we have already raised which we consider have good yielding and good straw characteristics."

THIRTY MILLION FOR IRRIGATION

A rare day in June, three years ago, was the 17th of that month, the anniversary of the battle of Bunker Hill and the birthday of the national irrigation law. And the net result of the latter, at the beginning of the present fiscal year, is an irrigation appropriation of $30,000,000, with an automatic revolving law under which the fund is constantly increasing through additions from the sales of western public lands and the repayment to the government by the settlers of all expenditures for irrigation construction.

Were there to be no additions to the reclamation fund, its present thirty million dollars would eventually reclaim the West. But with the large yearly additions which have been coming in, it is destined before many years to reach the $100,000,000 mark and become a vast fund for the redemption of Uncle Sam's desert lands for settlement. And could there be a greater work than that of making homes for the people?

Includes One-Half of the Country.—Almost half of the entire United States is comprised in the area covered by these great irrigation projects, rivalling the gigantic works of Egypt and British India. The following amounts have been apportioned by the Secretary of the Interior in the different States and territories: Arizona, $3,600,000; Arizona and California, joint projects, $3,000,0000; Colorado, $2,500,000; Idaho, 2 projects, $2,600,000; Montana, $1,900,000; Montana and North Dakota, joint projects, $2,350,000; Nebraska and Wyoming, joint projects, $5,750,000; Nevada, $2,740,000; New Mexico, $280,000; Oregon, 2 projects, $3,250,000; South Dakota, $2,100,000.

Should the recommendation of the President be carried out by Congress regarding the repeal of the timber and stone act and the enactment of a comprehensive forestry law, the irrigation fund would be greatly increased. The government timber sales during the last two years under the timber and stone act have been about three million acres at a uniform price of $2.50 an acre, much of the land densely forested with the finest Washington spruce and Oregon and California fir and redwood, worth, according to official reports, from $20 to $50 an acre.—Guy Elliott Mitchell.

Ups and Downs of Farmers' Life.—The Cultivator is in receipt of an interesting letter from an intelligent rancher at Los Gatos, in which he compares the life of the active farmer to the "professional" farmer who owns his farm, works it by proxy, as it were, depending on other business to tide him over loss of crops; to make improvements on his place, pay taxes and do whatever else is necessary to insure the success of his property. We know all about the trials, tribulations and sacrifices of the man, and his family, who depend on the annual crops to make their living. The difference between this man and the professional farmer is marked, of course. The former is in the business to pay, the latter as a recreation and pastime. But, ordinarily, both are anxious to realize from their investments while working from a different motive.

Our Los Gatos friend is prompted in his communication to say, among other things, that one drawback to the farmer, today, is the dictation of "unions," and another the multitude of holidays. Unions demanding wages that the farmer can not afford to pay, and holidays taking away from him time which he can illy afford to lose.

We grant all our correspondent says, about these discouraging conditions, and yet we know from experience that there is no life so full of genuine enjoyment, taking all things into account, as the life on the farm. It is independent. It is laborious, but full of pleasure. It lacks the mental strain which a professional career entails, and it gives health and vigor to the body. Happy is the young man who finds in the farm sufficient encouragement to make it a profession. When we compare the number of successful farmers, in America, to business men, and note the ups and downs of both, the preponderance is on the side of the farmer. In short, there are fewer financial failures in agriculture than in commercial life. We do not know of the daily bankruptcy in business, but we do know every man in the community who fails in farming—because it is unusual. The old saying is a true one, "stick to the farm and the farm will stick to you." If the farm be made attractive, as it can be, there is added pleasure in living on it. We still insist, that time may be found to make the farm attractive by keeping it clean and ornamenting with trees, shrubs and plants. That by making it attractive and homelike the sons and daughters may be made to love it, and by feeling an interest in it, stay with it, and the "old folks at home," until old enough to go out into the world for themselves.

* * *

Passing of John Hay.—In the death of Secretary John Hay, the country has met with a most serious loss. Probably no man in public life, since the time of James G. Blaine, possessed such a thorough knowledge of the diplomatic affairs of the nation, and was so well qualified to represent it on international questions as he. Since the days of Abraham Lincoln, he has been an active factor in shaping public matters, and his diplomatic mind has often shown its superiority when brought in direct connection with the most skilled representatives of foreign governments.

The country will miss the service of John Hay, probably more than any single man in public life, the President and one or two United States Senators alone excepted. He was able, in the broadest sense of the word. He was honest to the fullest degree, and while the older nations of the world had come to watch his diplomatic efforts very closely, because of their exceeding shrewdness, they never the less had the highest regard for his ability and integrity. He was one of the hardest working men in public life, and to his indefatigable toil he owes the shortening of his useful life.

* * *

Our Pauper Immigration.—The country ought to be aroused, and especially the authorities at Washington, by the report of Marcus Braum, who was sent to Hungary, to inquire into the nature of the emigration from that country to this.

Mr. Braum has filed his report with the authorities at Washington, and it is a most startling document. He states that during the last three years two hundred and eighty criminals, released from Hungarian prisons, were deported to the United States. More than this, he makes clear, what we have suspected, that there is a systematic understanding among officials to send to America the paupers, the moral lepers, the children of the worst classes, and this is systematically done by the use of fraudulent papers, both in Hungary and among the agents of the steamship companies.

What is true of Hungary is true of other foreign countries, which are sending us the worst of their criminals, their degenerate children and their paupers. Congress ought to wake up to the danger which confronts this country by the horde of tramps being foisted upon us, and so amend the laws as to put a stop to future immigration of the character described by Mr. Braum. We need quick, effective action.

* * *

The Future of Arizona.—The visit of the Congressional Irrigation committee to Arizona, and the recommendation it will make to Congress for a great system of irrigation for part of that State, is directing public attention to that country and its future possibilities. It is described by those who have studied its physical conditions as superior in general greatness to the arid districts of Colorado. If this be true, what may we not expect from the territory when it is watered by irrigation, as the country around Phoenix is. It will simply become a region unsurpassed in productiveness and unbounded in versatility of fruits and vegetables and grains.

The country possesses many charms in addition to its usefulness. We have before us a work written by Dr. J. A. Monk, of Los Angeles, descriptive of the physical condition and the life of the people who are pioneering Arizona. One is struck with the wonders portrayed in the Grand Canyon; the marvelous lights and colors of Meteoric mountain, a natural phenomenon, which scientists are studying today with more than common interest. The complete homes of that mysterious, prehistoric race, the cliff dwellers, the true aborigines who still adhere to their old rites, and refuse to mingle with the whites, are topics enticingly described in this little volume. One of the most interesting chapters of the sketch is the description of San Francisco mountain and the Painted desert, wherein are noted the several distinct life zones, running from the Arctic to the Tropic, within a distance of twenty-five miles. One wonders why people rush off to foreign countries to travel in lands whose physical phenomena do not compare with those presented in Colorado, South Dakota, California and Arizona. Far better to study the wonders of our own country than to rush away to foreign lands in which we have no national pride, nor interest.

But in Arizona, we are to witness, when the country is well irrigated, such marvelous development as shall create amazement even in the minds of those who are familiar with the growth of the great West.

* * *

Little Wastes on the Farm.—It is frequently said that if a business man in the city were to run his business with as little care as the farmer, he would become bankrupt within a year.

On most farms can be seen ground lying useless in large yards, drives, and occupied by old fences, which, if sown to some soiling crop, or used as a garden, would easily become the most productive spot on the farm. In other places may be seen acres of fertile land once used as an orchard, but now occupied by only a few scattered stumps, and grown over with weeds and briars, making a harbor for all pests that are noxious upon a farm.

Another expense that is directly felt, is the building and keeping in repair of fences. Many of these fences are entirely useless and a source of expense, directly and indirectly, through the ground occupied.

If a farmer only had some easy, reliable way of measuring his loss in that dirty brown water, slowly seeping from under his manure pile and running into the ditch, he would measure but once, and then begin to plan some way of carrying that fertility to his fields, instead of having it lost in the waters of our rivers and seas.

Another source of waste is the attempts of many farmers to raise crops on ground remaining wet and cold until late in the spring, and even if a crop is started, little is to be expected and less grown. How much easier it would be if that field was thoroughly tiled, even though it had to be done with borrowed money. One or two crops would easily pay the cost of the work; more fertility would be available, more thorough tillage could be practiced, and farming would be a delight instead of a drag.

But the greatest loss of all is that coming from or through the machinery of the farm. In a day's drive through some communities, a thousand dollars' worth of machinery, buggies, wagons, binders, mowers, etc., may be seen standing in the open, enduring the rain, the snow and the sun, dying a quick death from rust and decay. Such machinery is never at its best, and must soon be replaced. Such are only a few of the leaks on a farm, but those any man with a little gumption can stop.—L. A. Breckler, in Rural World.

Many dairymen possessing common cows get discouraged because they say they cannot compete successfully with more fortunate farmers owning blooded herds. To such let me say the remedy for improvement lies in your own hands. If you think you cannot spare the money to purchase a blooded bull, attempt to secure the services of one this season for at least a portion of your herd. Select only your best milch animals to be the mothers of your future grades, and you will soon have a herd of the latter of which no dairyman need be ashamed.

In order that a cow may give the greatest quantity of the richest milk it is necessary that she should be subjected to gentle treatment, never be hounded by dogs, never struck with sticks, never even be roughly spoken to, but petted and made much of as far as possible.

Just to be good, to keep life pure from degrading elements, to make it constantly helpful in little ways to those who are touched by it, to keep one's spirit always sweet and avoid all manner of petty anger and irritability—that is an idea as noble as it is difficult.—Edward Howard Griggs.

VALUABLE INFORMATION.

While in the office of the Horticultural Commission of Los Angeles county, we noticed some very valuable work on the part of Secretary Jeffrey, in preparing a topical index of annual Year Books of the Department of Agriculture, of which this commission has recently received a nearly complete set, dating from the time of the first appearance of these books under the Patent office management in 1847. The vast fund of information in such a large number of books is liable to be entirely lost unless it be arranged as being done by Mr. Jeffrey. It will mean a great amount of work and will take a long time to complete it, but in the end the commission will have a most valuable asset and aid in the prosecution of any inquiry which may come before it.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The apricot crop at the Novato Land Company's ranch is said to be very large this season. The peach crop is quite abundant and was sold last week for fifty dollars per ton.—Petaluma Courier.

It is claimed the Pajaro valley apple crop this year will total 3000 car loads and figured at $500 a car for all varieties. Such a crop will be worth $1,500,000. Packing houses will be kept busy during the season. An immense amount of work in "thinning" the crop to produce large sizes is in order.

Lindsay has at present seven large packing houses, several of which will be enlarged and improved and probably two more will be built before the opening of the orange shipping season. It is expected the various houses will be able to handle about forty cars a day.

The cannery at Dixon is putting up about 750 cases of apricots daily and employs fifty men and one hundred and fifty girls. Fruit is brought from the region about Dixon and also Vacaville, Suisun, Santa Clara and Placerville. The cannery has a capacity of 1000 cans per day when run at full limit.

In a bulletin recently published by the agricultural department of the University of California, the "resin compound is found partially effective on the San Jose scale and immensely successful on the brown apricot scale. The old "lime-sulphur-salt" wash was found the most effective remedy for the San Jose scale but of little use for the brown apricot scale. Experiments were conducted in the neighborhood of Hanford.

The Fresno Nursery Company of Fresno, incorporated December 1, 1894, has re-incorporated with a complete change of directors and stockholders. The new board of directors and stockholders are as follows: F. H. Wilson, president, 250 shares, $25,000; Thos Jacobs, Visalia, vice-president, 100 shares, $10,000; Morpney Jacobs, Visalia, 100 sares, $10,000; Chas. A. Chambers, secretary, 49 shares, $4900; W. A. Conn, attorney, one share, $100, making a total capital stock of $50,000, fully paid up.

W. C. Talbot of Porterville, horticultural commissioner from that district, who was here this morning, states that orange trees are still being set out in that section. About three more cars are to be planted on the El Mirador tract, formerly the Lewis Creek ranch, six miles east of Lindsay, about twelve cars having already been set out. The cars average about 700 trees to the car. The trees are irrigated well immediately after planting. Over ninety per cent of the trees are navels, the remainder being Valencias.—Tulare Register.

California's deciduous fruit shipments promises to total far beyond any other year. Prune growers are happy as there is a phenomenal sale of product in fresh state. The largest increase is on prunes and plums. Up to July first there had been shipped 270 car loads of apricots as against 94 car loads last year; 263 car loads of peaches contrasted with 85 car loads last year; 430 car loads of prunes and plums, as against 73 last season. As the season is nearly three weeks earlier this year than last, these figures are slightly misleading.

Wells Fargo's office is busy now packing and shipping Prunus Simoni and Tragedy prunes. They send them to their agents at different points between here and the Mississippi river, to be sold to the best advantage. F. E. Bearss, the agent, buys the fruit himself and does the packing. Returns from ten boxes of Prunus Simoni, containing twenty-five pounds in a box, netted him, Tuesday, after all expressage and expenses were paid, $9.90 for the ten boxes. Mr. Bearss pays one cent a pound, so it has to sell at $2.25 per box at least to insure him these returns.—Porterville Enterprise.

AGRICULTURE.

E. E. Pearsall has planted a thousand acres of Kaffir corn southwest of Brawley.

Hops are more backward this summer than ever before, being only about half the usual height on the poles.

The cantaloupe crop at Brawley has been a success the present season and plans are laid for the building of a cooling plant for next season.

G. W. Leek, writing to the Santa Rosa Republican, after an extensive trip through the Santa Clara country, strongly advises the Sonoma county fruit growers to hold their prunes for a three or three and half cent price.

A farmer near Silsbee, in the Imperial country, has been experimenting with corn for some time past, planting in February and a second planting in August. He has had fine roasting ears in June and December.

The board of supervisors of Amador county has passed a stringent ordinance looking to the eradication of the Canadian thistle, making it a misdemeanor for any land owner to allow the thistle to mature and disseminate seed on this land.

Over four hundred acres of valuable grain was destroyed by fire between Stockton and Lodi one day last week, as was miles of fences. Many fine residences were in danger and at one time a group of fire fighters were almost surrounded by the flames.

Sterling Peterson, a hop grower of Sonoma county, has contracted his hop crop for three years beginning with the present crop at 15 cents, next year at 14 cents, and the year following at 13 cents per pound. Hops are now quoted at 24 cents.

Our regular representative, writing from Kingsburg, says the country is in good shape, the farmers busy with the apricot crop, which is large and fruit of fine quality. The syrup company has it building at Kingsburg well under way and expects to begin work by the time the grape crop comes in. Grape syrup and unfermented grape juice will be the specialty. Crops around Fowler look well and orchards are in fine shape.

Last Friday night the second solid trainload of canteloupes was sent forward from our desert garden. Six cars from Coachella, four from Thermal and two from Brawley. The first solid train went east on Wednesday Before this time, Wells, Fargo & Co.'s express had carried car lots to the number of eighteen, besides smaller shipments. Verily, our old-time terror, the Colorado desert, is fast becoming the most fertile and earliest garden spot in America.—Redlands Citrograph.

LIVE STOCK.

Finley, Lake county, farmers are interested in securing a cheese factory for that place.

The usual dividend of five per cent has been declared by the United Milk company of San Francisco.

A creamery at Hayfork, Trinity county, which has been idle for several years, is now in operation.

The Taylorville creamery in Plumas county, which was started about a year ago, reports a very satisfactory business.

A carload of thoroughbred race horses purchased by Harry Stover at the Haggin sale at Sheepshead Bay, New York, arrived at Petaluma last week.

The Lockeford Creamery Co. leased its plant to the Crystal Cream and Butter Co of Sacramento last week. Patrons will probably receive a better price, as they nave been forced to throw their surplus upon the San Francisco market at whatever price the commission houses would pay. The new company commenced business the first of July.

MISCELLANEOUS.

The electric line between Lemon Cove and Exeter, has been completed.

Coachella's ice factory is turning out twenty tons a day for icing cars and refrigerating melons.

N. A. Clifford, of Santa Ana, has purchased 1700 acres of the E. O. Miller ranch, near Visalia, the consideration being $35.000.

Visalia's new beet sugar factory will be in process of construction within the next thirty days, the machinery loaded into nineteen cars having been shipped from Rome, New York, the 21st of last month. The plant will be considerably larger than first projected and will be capable of crushing a larger quantity if beets.

Owing to the cool weather prevailing so late in the season aplarists around Santa Ana now regard it as quite certain there will be a short honey crop this year. Early in the season it was thought there would be as high as 600 tons, but the estimate is now cut down to 400 and possibly 300 tons.

Around Santa Rosa hops are growing nicely, but the weather has not been warm enough as yet to kill the lice which, as usual, are prevalent in some fields. Some growers are using the soap spray, which seems to be the popular remedy, and probably more will do so if the pest increases and spreads to cause general damage.

A well 342 feet deep has been put down on a hundred acre orange tract near Success. Tulare county, and a pump and 20-horse gas engine installed. While the tract is nearly all under ditch there are two months of the year that the ditch runs dry and water must be had or the land is worthless for citrus fruit growing.

J. W. Barbour states that he and his partner, H. Clawson, will harvest between 50,000 and 100,000 sacks of grain on their Lake lands this year and on the lands they have rented While the rust has materially reduced the crop of wheat from what it would have made, the barley sown has yielded heavily and the grain crop is a paying one. He says that if, for the coming ten years, he could be assured of as good returns as he and his partner will realize from their grain harvest this year, he would be well satisfied.—Hanford Journal.

The California Western railroad and Navigation company has been incorporated for the purpose of constructing a railroad in Mendocino county, with a terminus at Fort Bragg on the ocean shore. The road is to connect with the Union Lumber company's railway and is to have a length of sixty-five miles. The capital stock is fixed at $1,000,000. The list of directors is Duncan McNee, Miles W. McIntosh, Charles H. Weller, H. M. Cochran and Max Goldberg.

Our represetntative writing from Santa Rosa under date of June 3, says: "Today marks an epoch in Santa Rosa electric lines, as cars on the Petaluma & Santa Rosa line, for the first time run down the main street and a fine appearance they made. Previously cars had stopped at the depot soon after entering the city limits. Hopes are entertained that the road will eventually be extended from Petaluma to San Francisco, thus giving excellent service to and from the city for Santa Rosa.

The present weather is greatly beneficial to the hop vines which have come up this year, and prospects are brightening for the coming crop. At the present time it is estimated that the 1905 crop will be about as large as that of last year, 19,000 bales. This figure may be increased slightly, as Sonoma hops generally turn out better just at the last of the season than they promise during the season. A conservative estimate of the amount of hops now being held by growers in Sonoma county is fourteen hundred bales.—Healdsburg Enterprise.

A Cultivator representative writing from Santa Rosa, Sonoma county, says the fruit crop is a little short this year. "No cherries nor pears with prunes far below an average crop. Dairy people, however, have had a good winter, abundant rains making fine pasture which is only beginning to dry up. No other feed is necessary for the dairy herd during the wet season since the first of January. One subscriber mentioned he fed nothing the whole five months and the third month from calving jotted down the butter figures from one Jersey cow for twenty-two days which added forty-two pounds. Hops will not be a large crop. Many 'hills' are missing, though with warm weather from now on what come up will do well and the product will be a good quality. If like conditions are general prices should be satisfactory."

C. H. SESSIONS, ASSOCIATE EDITOR

REPORT OF THE DAIRY BUREAU.

The fifth annual report of the State Dairy Bureau is just from the press of the State Printer, and covers the past two years' work of the Bureau. It refers to the prosperity that has been experienced by those engaged in various branches of dairying as the result of exceptionally good prices which have come to them for the products of the cows. Also, for the impetus this prosperity has given to the expansion of the industry, which is bringing dairying to the front as one of the leading industries of the State. This, the Bureau says, is giving California rank as one of the important dairy States of the Union. The report refers to the fact that for several years prior to '95 there was a vast quantity of oleomargarine sold in the State, but this has now been almost entirely discontinued by the heavy tax placed upon it when colored and by the fact that people will not buy the stuff uncolored.

Since the national law has come into effect, a few years since, the butter production of California has almost doubled in quantity and prices have been profitable as a rule in all markets.

Regarding the growth of the 'margarine production the book gives a table showing the number of pounds produced each year in the United States since '87. In this it appears that from 21,000,000 pounds which were produced in '87, it has increased to 126,000,000 pounds in 1902. In 1903 this was nearly cut in two and in 1904 again amply reduced so that the total of the United States production was last year about 48,000,000 pounds.

Reference is also made to the enforcement of the law relating to the sale of "renovated" or process butter. This class of butter, as its name indicates, is usually made from butter unfit for consumption, on account of its age or from other influences that have destroyed its palatability. By melting this butter and by various processes of eliminating the products of fermentation, and churning the melted oil in milk, an article is produced that is pure and temporarily free from objectionable rancid flavors, but if exposed to ordinary temperature it almost immediately loses its good quality. This temporary sweetness enabled makers and dealers in the past to conceal the true character of the article, and much of it was sold for the superior grades of butter, to the injury of producers of fine butter, and at the same time a market was created, through the renovating business, for large amounts of butter that was improperly made, or allowed to become unmerchantable from age."

The laws against this stuff have been passed in nearly all States and the one in this State is being rigidly enforced against sale of such renovated butter.

A table is given showing the output of the various dairy products from the counties of the State. This shows the total of creamery butter for the year of 1903 of 24,591,271 pounds. Of dairy butter, of a little more than 10,000,000 pounds. For the year of 1904, 26,433,060 pounds of creamery butter were produced and a total of 9,000,000 pounds of dairy butter. This showed an increase of about 2,000,000 pounds of creamery, and a shrinkage of nearly 1,000,000 of dairy butter. The banner county in production of creamery butter is Humboldt which produced last year 3,771,135 pounds while of dairy butter it produced only 22,560, or a total of 3,793,695 pounds. On the other hand, Marin county produced 1,493,733 of creamery butter, in the same period, but 2,319,504 of dairy butter. This makes her total 3,813,237, or slightly more than the total of Humboldt county. Doubtless the income of Humboldt county would be materially greater than that of Marin from the fact that creamery commands a higher price in the market than does the dairy.

The next county on the list, and one between the two above mentioned, is Sonoma, which last year produced a total of 2,421,680 pounds. The county producing the smallest amount in the State, next of course, to San Francisco which produces practically none, is Shasta, with a total of 5,820 pounds.

It can be noted that the greatest increase in butter production is largely in the lower San Joaquin and Sacramento counties. For instance, San Joaquin, which in 1903 produced 963,151 pounds, last year produced 1,015,568. Stanislaus county, which in 1903 produced 1,159,561, last year produced 1,564,749. Sacramento county produced in 1903 1,341,867 and in 1904 1,508,293 pounds. Merced forged ahead from 905,622 in 1903, to almost double at 1,563,771. Shasta, which we spoke of above as being the smallest producer in the State, shrunk almost three-fourths in its total production. Los Angeles county shows a shrinkage from 1,996,438 to 1,630,069. This case, however, is explanable by the fact that Los Angeles city is increasing in its demands so continuously for fresh milk and cream that creamery production will continue to decline. Fresno county shows an increase from 1,393,158 to 1,619,746.

"The remarkable but steady growth of the State's butter production, as shown by the figures, is one of the conspicuous features of California's industrial life. It goes to show that her citizens are awakening to the fact which they have heretofore been slow to recognize, that almost every county in the State has areas adapted to dairy farming not excelled by any part of the world, while in the counties located in the Sacramento and San Joaquin valleys only the application of irrigating water is required to make almost the entire area one alfalfa meadow for eight or ten months of the year. Not only are Californians learning to appreciate the possibilities of the dairy business, but during the past few years these possibliities have attracted many settlers from other States, and what were formerly large grain growing areas are now numerous small dairy farms."

"A feature which is still retarding a still more rapid development of dairying is the difficulty of securing competent labor to work on dairies. This drawback, however, has had one desirable effect, in that it checks a tendency on the part of our citizens to conduct dairy enterprises on an extensive scale with large numbers of cows; while on the other hand, by maintaining prices which might not be possible if such extensive dairy enterprises were readily practicable, there has been much to encourage the dairyman operating on a small scale and doing the work himself assisted by his family. It is this that has brought about a very desirable tendency, in many parts of the State where dairying is becoming conspicuous, of converting large holdings of land into numerous small farms, whose owners are invariably very prosperous."

"In the two years covered by this report a large amount of butter has been shipped into California from the East. Only figures for the year ending June 30, 1904, have been obtainable, and these may possibly not include all that arrived, as they account only for full carload shipments. They show 3,340,000 pounds, or almost ten per cent of what our State produces."

The total cheese production of the State shows a shrinkage in the two years. 1903 the output was 7,218,639 pounds while last year it was 6,133,898 pounds. In this respect there is difference between the butter and cheese production largely in favor of the butter which has been increased so satisfactorily.

The average price in the City of San Francisco for the year 1903 was 27.8 cents per pound, and in 1904 23.3.

Col. J. M. C. Marble, Pres. E. E. Moore, V. P. and Gen'l. Mgr. J. E. Marble. J. E. Fishburn W. C. Marble, Secretary.

TUBULAR--or "Back Breaker?"

When you see the waist low Tubular you can't be driven into buying a back-breaking, "bucket bowl" separator. **Can and crank are just the right height on the Tubular.** Here is the largest Dairy Tubular along side four "back breakers." The girl with her hand on the Tubular is 5 feet, 4 inches tall. This is an exact reproduction from a photograph. **Which kind for you?** Makers of "back breakers" try to get their cans low by setting the cranks low. **High cans** break your back backward—**low cranks** break it forward. Unless you are a double jointed giant, you'll find a high can is no joke. To show you how high these "back breaker" cans really are, when the machines are set high enough to turn easily, we raised these "back breakers" 'til their crank axles were level with the Tubular crank axle. "Back breaker" makers don't like this picture—**it's too true.** They try to squirm out of it. **You wouldn't like turning cranks as low as "back breaker" makers put them.**

The low can is only one of many advantages Dairy Tubulars have over all others. Dairy Tubular bowls are simple--"back breakers" are complicated. Tubulars are self-oiling--no oil holes to fill up. "Back breakers" are oil drippers and oil wasters. To learn a lot more about Tubulars, write today for catalog N-260

GUY H. MILLER RIVERSIDE, CAL.

A GREAT HERD.

The Cultivator has often spoken in its columns of the work of the Riverside Premier Herd of Holsteins. Also during the last few months of the fact that W. C. Hunt, formerly of Liverpool, New York, had become manager of the ranch. It has been plain that since Mr. Hunt has taken charge of the herds of the Messrs. Pierce, new life is being installed into the management and that Mr. Hunt is no novice in the work which he has taken up.

Regarding his work at Liverpool, where he owned and placed on a magnificent footing the Village Farm Herd, we quote from a writer in a recent issue of the Holstein-Friesian Register:

"During the past year we have had frequent occasions to go through Mr. Hunt's stables, and have thus had opportunity to become somewhat familiar with the different animals; but not until we took the time to consider each separately and to look more particularly into records and breeding did we realize fully what a wonderful work Mr. Hunt has been accomplishing in the development of his herd. Today the visitor to Village Farm sees that uniformity of type and the general high standard of excellence which are supposed to be manifest only in the long established herd, representing in its development the best efforts of a life time.

How Mr. Hunt has been able to concentrate the work of a life time into a few short years, is a question not readily answered; but those who are familiar with his ability in feeding and caring for stock, his skill in selecting, his attention to details and his untiring industry and remarkable capacity for work, can understand to some extent why he has been thus successful.

The herd has attained its present high standing not as a result of what money can do in brining good cattle together, though Mr. Hunt has been a liberal buyer, but is representative rather of judicious selection, correct management and careful forethought. Mr. Hunt has repeatedly demonstrated his own skill, and the superiority of his cattle, by the wonderful official tests that have made the name of Village Farm Herd famous, and the herd can now present an array of records in some classes that no other in the world can approach. We have referred to the fact that the herd is more than a mere collection of high-class cattle. Its members conform to a uniform standard, not only in type, but in breeding.

We feel that Mr. Hunt's departure from our midst is a distinct loss to Holstein interests in the East, and we believe our fellow breeders will join us in wishing him continued prosperity and success in his new career."

* * *

We recently wrote Mr. Hunt at Stockton regarding the qualifications of the Holstein cow for the ordinary dairy farmer in California and asked him to say as good a word for his favorite breed as he had for our readers, and we are pleased, indeed, to give room for the reply, as follows:

Editor Cultivator: Replying to your kind favor requesting a few words from me relative to the qualifications of the Holstein-Friesian cow for the ordinary dairy farmer of California, I will say that in my judgment that too much cannot be said in her favor for this purpose. In the first place she carries probably the greatest amount of vitality, rugged and healthy constitution, together with larger size, than any other breed of dairy cows in the world. Naturally then, of course, the Holstein calf maintains the same rugged constitution from the start, making rapid growth and development on cheap feeds where others of the smaller breeds and weaker constitutions require milk from the cow for several months. I believe that it is now the recognized fact that the Holstein cow can produce a pound of butter at less actual cost to the average farmer and dairyman than any other cow in the world, and she can certainly produce 100 pounds of milk with a still greater balance in her favor.

Probably no dairy cow in the world can find any section of any country so nearly like her native heath as California is to the Holstein. The main difference between the conditions for dairying in California as compared with those of Holland and Friesland are that we have more sunshine here and the winters are much more mild, which certainly should be to the advantage of any breed of dairy cattle.

Besides the above advantages mentioned, there is another that should not be lost sight of and that is that this breed of dairy cows are able to and will consume more coarse fodders, such as are grown on the average California ranch to better advantage and with greater net returns than can be obtained in any other way. For instance, to illustrate this: Here on the Riverside Ranch for the three months of April, May and June, we have averaged 140 cows in milk of pure-bred Holsteins, and on grass alone, with one acre of rye grass pasture to each cow, they have averaged over 2700 pounds of milk each, or over 900 pounds of milk each per cow per month, and this on grass alone, and in my judgment these results could be obtained with no other cow than the Holstein. With good alfalfa hay to feed when the pastures begin to get short, this same large production can be kept up for the greater part of the entire year, and it is one of the greatest desires of the Pierce Land and Stock Co., not only to make this herd of Holsteins at Riverside Ranch a source of financial profit to themselves, but to show every dairyman on the Pacific Coast that there is money in milk when an abundance of coarse fodder is supplied to the Holstein cow.—Pierce Land & Stock Co., W. C. Hunt, manager.

DISEASES OF SHEEP.

Many years ago the only disease sheep were known to have was foot rot. Later scab developed, and it was thought to have been the result of neglect.

All old diseases have been met half way with good remedies found for them. Some of the later disorders of sheep have not yielded so readily to treatment.

The diseases which have been found most troublesome and stubborn are those occasioned by parasites. Of course there are several different species.

Scab is also caused by a parasite, but it is external rather than the most dangerous, which are internal. The later are: Stomach worms, lung worms, intestinal worms, tape worms and nodular worms.

For tape worm, oil of male fern seems to be the favorite remedy, a teaspoonful being a dose. Two teaspoonfuls of powdered areca nut is also a good remedy.

A solution of 1 per cent coal tar is also a good worm remedy given in doses of two to four ounces.

A FINE ADVERTISEMENT.

A handsome picture of a foothill orange grove at Porterville, occupies the front page of the June 9th issue of the California Cultivator. The Cultivator claims a circulation of over 14,000 papers, and is widely read, and is entitled to the thanks of this county for so fine an advertisement. It will no doubt be the means of bringing many homeseekers to this section.—Porterville Enterprise.

The Cultivator is glad indeed to call attention to agricultural and horticultural accomplishments of various parts of the State and it appreciates the appreciation of the section referred to. One point worthy of correction are the figures given. The right figures are right, only misplaced. Instead of 14,000 the Cultivator has 10,400 but proposes to pass the figure which our courteous contemporary credits us with.

Watch us grow.

MILCH GOATS.

Dr. J. H. Hester, of Santa Barbara, was a caller at the Cultivator office this week and informs us that he has ordered a bunch of the Nubian goats from Mr. F. S. Peer of Ithaca, New York. Mr. Peer is a noted stock importer and is now in Europe making selections of certain dairy animals and goats, and it is on him that Dr. Hester is depending to make selection of some heavy milkers of this strain of milch goats. The Nubian is a native of upper Egypt, but for many years has been bred in England and in Holland and is proving a magnificent animal. As the Cultivator has remarked before, we believe there is a great future for this industry and that the man who enters into it now and introduces thoroughbred stock will be in line to reap a harvest when the merits of this stock become better known.

CATTLE QUARANTINE.

Editor Cultivator:—Will you please inform me if there is a quarantine against shipping cows from Orange and Los Angeles counties to San Joaquin valley? If so, when will it be raised, and what will be the requirements.—E. C. N., Santa Ana.

Yes, there is such a quarantine, and as to when it will be raised and the privilege of free shipment from points south of the line permitted to other sections of the State or other States depends upon the counties within the quarantines. If the supervisors would make rigid ordinances as to stamping out the disease from the counties and see that the ordinances are enforced, the authorities of the Department of Agriculture may be inclined to remove this quarantine entirely. But while the condition prevails which has for the past few years, so long will the quarantine prevail. The line has for several years been crowded farther and farther south until now in the coast counties it is coming close to Los Angeles county while inland it bends north even beyond the city of Fresno. The counties in question have eradicated the Texas fever tick by dipping and careful culling of diseased cattle until they have conquered this dread of the stockmen. Disinfection once done, and thoroughly done, inspection by agents of the department is made and the quarantine is raised. From the condition of things in the counties inquired about, we assume it will be several years before it will be raised.

BILL NYE'S COW.

Bill Nye, the humorist, once had a cow to sell, says the Philadelphia Ledger, and advertised her as follows:

"Owing to my ill health, I will sell at my residence, in township 10, range 18, according to the government's survey, one plush raspberry cow, aged eight years. She is of undoubted courage and gives milk frequently. To a man who does not fear death in any form she would be a great boon. She is very much attached to her present home with a stay chain, but she will be sold to anyone who will agree to treat her right. She is one-fourth short-horn and three-fourths hyena. I will also throw in a double barrel shotgun, which goes with her. In May she usually goes away for a week or two and returns with a tall, red calf with wobbly legs. Her name is Rose. I would rather sell her to a non-resident."

MILK DIET.

The strippings taken immediately after milking is the most valuable thing known to build up a person who is thin or upon the verge of breaking down.

It should be followed up regularly twice a day.

It is especially valuable to persons who have a tendency to lung affections.

It can be taken and assimilated in this way fresh from the cow when cold milk cannot be taken at all.

Buttermilk is very beneficial in many kinds of stomach troubles and is healthful for everyone.

The best wool and the best mutton are obtained from sheep that has been kept growing all its life.

Sheep restore to the soil a larger proportion of the elements than they take from it in grazing than do any other stock.

It is said that soil upon which they graze affects the quality of the wool. Clay soil produces the best, sandy soil the second best, and lime soil the most inferior.

Sheep are very much like other animals; if they are to be good sized, tender and thrifty, they need to have a good chance while young, so that they may grow rapidly.

The best way to clean a clover pasture where the young sprouts are becoming troublesome is to turn in the sheep. If you happen not to have a flock, buy them, but buy good ones.

While sheep will get more sustenance from poor land and at the same time do the land more good than any other stock we may possess, it must not be forgotten that they will also repay liberal feeding.

AN APPRECIATIVE LETTER.

Editor Cultivator: Your article, "Hoven in Cattle," put in at our request, was very much appreciated and we write thanking you for taking up the subject so thoroughly. We think those directions clear enough to be followed by anyone, and, if the occasion requires, we feel that we know what to do, and can do it with a confidence that we could not have had before.

So, thanking you for helping us on this important subject, and no doubt helping many other readers of the Cultivator, we remain, yours truly,

JOHN STUBBLEFIELD,
FRANCIS I. PAGE.

A little extra time spent in preparing butter for market is time saved, not lost. Bear in mind that you are building a reputation that will cause your butter to be sold readily at all times.

DAIRY COWS FOR JAPAN.

K. M. Koyu, and his secretary, W. Iijima, two Japanese gentlmen, were in Ottawa a few days ago conferring with Dairy Commissioner Ruddick in connection with their visit to Canada to purchase about forty dairy cows for experimental purposes on Mr. Koyu's dairy farm in the land of the Mikado, and wishes to give Canadian cattle a trial. In his search for suitable animals, Mr. Koyu has been aided greatly by Mr. Ruddick, who says that the foreigner has an excellent idea of what constitutes a good dairy cow. Ayrshires and Jerseys are being purchased principally.—Farmers' Advocate.

Speak well of a man before his death and thus give him a chance to return the compliment.

INCUBATION ON SHARES.

Editor Cultivator.—I am incubating eggs for a neighbor on shares. Please state in the next issue of the Cultivator what is an equitable division of chickens. How long should I feed and care for them before dividing?—M. J. G., University.

The answer to that question depends on several things. Are the eggs valuable, that is are they from high bred birds which will give a fair percentage of prize winners at a show? Or are they ordinary well bred stock, or are they the barnyard fowls? Assuming the eggs to be from ordinary stock, without any great value to the eggs, if you should keep the chickens for one week after incubation, two-thirds of the chickens hatched should go to the one furnishing the eggs and one-third retained by the incubator.

Like a beautiful flower, full of color but without perfume, are the fine but fruitless words of him who does not act accordingly.—Buddha.

Aiken and Coe, of the Bamboo Poultry ranch ,at Glendale, telephone the information that the mammoth incubator recently spoken of at some length in the columns of this paper as being under construction, is now in operation and is proving a complete success. The temperature is easily maintained and Mrs. Aiken informs us that, excepting to turn the eggs, it would not be necessary to visit the incubator more than every two or three days. The 'phone number of the ranch is Home 701.

With money you can move the gods; without it you can't move a man.

.. Summer Hatching ..

Pays us—it may interest you if you if you are not overstocked. An August hatched cockerel from these yards sold for $15 this spring. Eggs after July 1, $1 for 15, $5 per 100, including the eggs from our prize winning birds.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

DANGER SIGNALS.

Danger signals are already beginning to fly and we are only as far as as the "Glorious Fourth!" I am already getting sad letters from poultry breeders, especially from turkey raisers, telling of the dread disease, "Roup." It is early in the season for roup, and I am very sorry to say it is an indication that we are threatened with a long and very disastrous epidemic of that much dreaded disease. The thing to do is to follow the example of the wonderful little Japanese and "prearrange" to defeat the enemy. How is that to be done? What are the first indications of roup? And what causes it? Oh! how can we escape from it?

I remember reading long ago "there are three causes of roup: Firstly lice, secondly lice, thirdly lice." I would add a fourth to that and say and fourthly anything that gives a cold such as a draught through a crack or knot hole, or the fowls sleeping where the night breeze will blow under their feathers or chill them.

I propose to consider today the first, second and third causes, especially as I have a letter from one of our readers containing a large louse and asking me what it is.

It is a louse, my friend, one of the many kinds; I do not know its given name, but it is one of the slower moving members of that interesting and most troublesome family.

It a big family; there are too many for me to name or even describe them in general. Gray, blue, yellow, black, red (mites). Lice that run like lightning, others that bury their heads and stay still (on the chick's head), others that are lazy and saunter round the feathers in a leisurely manner. These lay their eggs on the outer edge of the fluffy feathers. Some feed on the feathers and some on the blood of their unfortunate host. Some will even leave the fowls and visit their unlucky owners. They are all pernicious parasites, and if we want to fight our enemy roup we must exterminate them. We must take no chances; we must remember that this is a lovely climate for lice and all external parasites and must lend our energies to get rid of them, and to keep rid of them.

Cleanliness is of course the first requisite. The lice and especially the troublesome hen flea and other parasites breed in dirt and droppings. The flea is found in neglected henneries on sandy soil. Dirty nests, cracks, dust and dark corners are their favorite breeding places. They produce irritation of the skin and in young birds the growth may be permanently stunted. Very young chickens may be killed by them.

For treating flea bites, bathe the bites in vinegar and water, or lemon juice and apply carbolated vaseline. To free poultry houses and yards of fleas, use white wash freely, adding a pint of crude carbolic acid to every twelve gallons of whitewash. Spray it or slop it thoroughly into all the corners and cracks. Use tobacco dust and moth balls in the nests. Dark, dusty places in the poultry yard afford favorable breeding places for fleas. These places should be soaked with hot soapsuds and boiling salt water to kill the young fleas.

* * *

Lice.—There are nine varities of body lice affecting poultry. Each variety has some favorite part of the fowl's body which is its camping ground in preference to other parts, and it seldom tresspasses on the neighboring claims. There are, however, two varieties which are wandering lice and may be found on all parts of the fowl. These lice not only travel from fowl to fowl on the roosts at night, but frequently leave the fowls to attach themselves to persons handling them and even to the walls of the hen house. Lice spread rapidly, one infested bird being capable of spreading the vermin through a large flock. In young fowls they cause dumpishness, drooping wings, indifference to food, and may stunt or even kill the chicks.

One of the best means of preventing lice is a dust bath. This bath should be a wallow of freshly turned earth, mellow and slightly damp, out of doors under a tree in the summer, or in a box eight or ten inches deep in the hennery in rainy weather. Provided with a good dust bath, healthy hens will almost keep themselves clean from lice. Not so the cockerels; they are careless about their toilets, or afraid of taking sufficient dust baths and must be frequently examined and, if necessary, dusted.

* * *

If fowls are badly infested with lice they should be well dusted with a good lice powder, of which there are a number on the market.

Two good powders can be made as follows: To one peck of sifted coal ashes add one half ounce of 90 per cent carbolic acid; when thoroughly mixed add an equal bulk of tobacco dust. Or, take half a peck of sifted road dust, four fluid ounces of any good lice killer; mix thoroughly and add an equal amount of tobacco dust.

The roosts may be painted with liquid lice killer and the fowl placed in a box, the floor of which has been painted with lice killer and the top covered with burlap, care being taken not to smother the fowl. The nits or eggs hatch about every five days, so for badly infested fowls, feathers having nits upon them should all be pulled out, and the treatment should be repeated until all the young lice are exterminated.

An excellent plan in warm summer weather, just at the commencement of the moult, for getting rid of lice, is to immerse the fowls in a diluted kerosene emulsion, wetting them thoroughly to the skin. Bear in mind three things:

First, the dipping must be done on a warm, bright sunny morning, when the thermometer is not lower than 80 degrees in the shade. Second, the water should not be over blood heat.

The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.

Sumptuously illustrated catalogue free; write for one at once. Send for our poultry supply catalogue No. 47, describing our line of supplies. Everything for the Poultrymen.

Third, and most important, every solitary feather must be made soaking wet, else you will not make a clean job of it. In dipping all fowls having heavy plumage, like the Brahma and Cochin, the feathers must be raised with the hand and the water allowed to thoroughly wet the bird to the skin; this takes from one to two minutes for large, well feathered fowls. If a dry feather is left, there will be lice on it. Do not dip the head under, but dip all up to the eyes and if the fowl will not hold still use a small sponge and wet the top of the head. No one who has fowls troubled with lice need fear to try this, it is very effective.

Emulsion.—The emulsion for the dip is made as follows: In one gallon of boiling water, dissolve one bar of laundry soap, or one pound of soap powder. When the soap is thoroughly dissolved, take it from the fire and add one gallon of kerosene, and one pint of crude carbolic acid. Churn, or stir vigorously until cold. Take one quart of this and add to it ten quarts of warm water. This is the same emulsion that I use for spraying the henneries, and it is death to mites.

* * *

EDITOR'S QUESTION BOX.

Cannibalism—(New Beginner): What can I do to prevent young chicks from picking each other's toes and roots of tails. The habit commenced when four or five weeks old. I feed Midland No. 2, a little wheat and chopped cabbage with a little blood meal. Have only taken the Cultivator a few months and find it a great help.

Answer.—Keep your chicks busier. They get into mischief (just like humans) if they have not enough to do. Feed them a little finely chopped meat and lots, lots of lettuce or other succulent green food. At this time of year chickens crave something juicy and if you do not supply it they will take each other's toes. Let their principal food be grains fed in chaff or straw or alfalfa hay; give them something to scratch in and something to scratch for. Feed liberally.

* * *

Indian Runners.—(H. E. J.) Have read your article in the Cultivator on Indian Runner ducks and bought a sitting from Mrs. Hungerford which all hatched; also some from a neighbor; now have 53. Seven have black bills, others white. The white bills are the noisiest. Would you be so kind as to tell me which is which, and what you think of this plan of raising ducks? I have a fourteen-acre ranch, walnuts, oranges and alfalfa. My plan is to fill a 230-egg machine the first of the month and a second machine the 15th, put the 200 (or less) ducklings in three broods for two weeks until the second machine hatches, then run them into their larger pens and fill No. 1 machine again. Will keep machines going continuously. At the end of eight weeks will sell first lot of 200 (or less)—a continuous performance, selling at the end of eight weeks. I believe I can make them weigh five to six pounds by that time. By the market report each week I see that the price ran from ten to fifteen cents on an average last year. My ducks should be laying by September if they are not all drakes. I cannot afford a large plant, so by this plan I can turn off a large number of ducks in a year. If the price stays up, I should think I could make good wages at 400 ducks a month. I prefer to raise ducks to chickens as they can be kept out of mischief much easier.

Answer.—In reply to your letter the first indication of the sex of ducks is in the voice, the female having a louder voice than the male. The male only makes a sound like a coarse whistle. The bills of the Indian Runner females are darker than those of the males. The young males are usually larger than the females of the same age.

You are right about the Indian Runner ducks being easier to raise than chickens, for they never have roup or lice, which are our two great plagues in the chicken business. As to your plan, it looks good on paper, but I

Trophy Winners at 1903 Los Angeles Show

In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.

My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

WARNING!!

THE JUBILEE INCUBATOR CO.

now of Oakland, California beg to announce the removal of their factory and business to SUNNYVALE, SANTA CLARA COUNTY, CALIF., 40 miles south from San Francisco, where a large plant is being constructed.

The Jubilee will possess the finest works and most splendid facilities to be found in the West, and also ample room for further expansion.

This move is of the utmost importance to every Poultryman on this Coast. "The Why and the Wherefore" is fully explained in the **JUBILEE ANNOUNCEMENT.** If you have one chicken or 5,000 you should have that Announcement.

You are no doubt curious to know **why** we moved to **Sunnyvale,** and where **you** will be benefited, Get the **Announcement.** We mail it free. Now get it,—we promise you it will be interesting.

TAKE NOTICE. On and after Aug. 1st our address will be

SUNNYVALE Santa Clara County **CALIFORNIA**

Until then, the same as for many years:

JUBILEE INCUBATOR CO.

Jubilee Incubators and Brooders, Poultry Supplies

fear would not pan out quite as good as it looks. For one thing, the ducks do not lay during September and October, and their eggs are not very fertile until February. We can only hatch with certainty for not over six months or from January to July inclusive. You will have seen by my account of the experiments with the ducks at the Government Experiment Station in New York that they need and must have more animal food than chickens; also plenty of green food. If you are so situated that you can supply them with these you can always be sure of a market for ducks. I have often thought that residents at or near Redondo or some of the beaches where plenty of fish could be had very cheaply might do very well with Indian Runners. Your plan of hatching every two weeks might do all right for six months but for the other six months you would have to do something else.

GROWING CHICKS.

Much has been written on growing chicks. Probably many on almost the same lines with but different wording. Some beginners have been able to grasp the writer's meaning—others have not. There is only one right way. By attending to the many small things that many think unimportant. We have seen experienced poultry raisers feeding well, housing well, and yet neglecting watering—in our mind one of the most important of all. From the beginning the baby chick should have clean fresh water before it at all times. They drink many times during the day, the first thing in the morning and the last at night. As soon as possible get the chicks on the ground that they may obtain natural green food which they crave. Feed fine cracked grain, wheat, oats, millet, barley the first eight weeks, with good meat scraps every day after they are ten to fifteen days old. Use judgment in the feeding of meat, as the excessive use of it sometimes causes weak legged chicks. At eight weeks the chicks are ready for a mash once a day, using bran, shorts, a little corn meal, the meat scraps being fed in the mash three to four times a week. Cooked potatoes, etc., are good if used now and then for a change. We do not believe in heavy corn feeding to growing stock unless forcing for broilers or market. Neither do we believe in having meat scraps before the chicks all the time, for when they are hungry one can see them going for the scraps in the hopper to take the place of grain they should eat. Keep them a little hungry at all times. This induces them to keep active in search of food, making them exercise, which is essential to promote strong growth. Even on a good free range they do not get bugs or worms enough, and the meat should be fed as stated above. Never neglect the grit and charcoal. While nice chicks have been raised without it, it is better to be on the safe side and have it before them at all times. See that they are supplied with shade. The growing chicks need shade as well as sunshine. Do not keep above fifty in one house, and if possible give them all the run they desire. We have grown June-hatched chicks that made good winter layers and proved valuable birds in the breeding yards. But the beginner seldom has the same success, for the reason that during the five or six months they have a check—sometimes two or three. Chicks once checked can never regain what they have lost, be it either through poor feed, chilling, crowding, overfeeding, etc. We do not believe in forcing maturity. But with a steady, healthy growth fowls will prove earlier layers, more steady and longer lived as to egg production. Separate the male birds as soon as possible that the pullets may have the range or yards to themselves. Keep them contented. A happy contented chick is a growing one. Keep the house clean. It need not be cleaned every day. Use judgment in the management of your fowls. If brooder chicks you will not be troubled with lice if every precaution has been used. If hen raised use one quart of kerosene to one ounce of carbolic acid for the little red louse. This is also a good disinfectant. Purchase good, clean feed. It pays in the end. At the end of the fifth month the fowls can be yarded in their permanent home, that they may become accustomed to their new home. In clean, comfortable houses, fed with good, clean feed, the fowls are happy and contented and prove profitable. Attend to the many small details. The small ones count, and poultry raising will prove a source of income never realized by those who give their fowls indifferent care.—Inland.

LIMING EGGS FOR HOME USE.

The Cultivator has frequently given formulas for putting up eggs in solution of water glass as doubtless the very best preservative for eggs ever devised. However, the old lime pickle is still somewhat used, and the formula for its mixture may be desired so we quote as follows as given by a writer in the Orange Judd Farmer:

Take one pint lime, half pint salt. 1½ tablespoonfuls cream of tartar, and mix well in a porcelain lined kettle. Pour two gallons of boiling water over this and stir well until dissolved. When cool put in a stone jar (will not keep in wood) in a cool place in basement of cellar. Have the eggs perfectly fresh and clean. Wash them if soiled. Put in clean, cool water when taken from the nest, and then into the brine.

Large jars are best. I usually put 30 dozen eggs into this brine in July and August, and use them through the winter until June for bread, cake, etc. The only difference from a fresh egg is that when you break the egg the white is thinner and has a little odor of lime.

The last few words show that this pickle is, to a certain extent, objectionable, and we think the water glass solution will have the greater number of users.

BUMBLEFOOT.

Bumblefoot is a common disorder where roosts are placed too high. Hens are often hurt in the foot and germs get in the wound which cause the bumblefoot. It is difficult to cure, the fowls usually not being worth the trouble to treat them. The treatment consists in making an incision in the foot where the swelling appears to be, placing the fowl on clean straw, washing with warm water containing carbolic acid, after which nitrate of silver should be applied.

Any one will do well to invest in a barrel of lime, keeping a goodly supply on hand at all times. In the first place slake enough to make half a barrel or more of whitewash of the consistency of very thick cream. This is to be thinned when used on the coops or in the houses. Keep this on hand. It improves with age and will be found exceedingly useful. Nothing brightens up the premises more than good whitewash. Then there will be found in air slaked lime one of the best disinfectants. Scattered in the hen houses under the roosts, it will destroy foul odors and disease breeding germs, and is an excellent article to sprinkle on low, damp places during the rainy season. Once used, lime will be found indispensable. It may not be worth its weight in gold, but it helps win the shekels for which all poultrymen are striving.—Petaluma Journal.

Most eminent men's conviction is, that there is no sounder or surer way of increasing business than serving one's present customers faithfully; this done, they are sure to say so to their friends.

THREE GREAT POULTRY NECESSITIES

PRUSSIAN POULTRY FOOD
The Great Egg Producer
Keeps Hens healthy. Helps them lay. Prevents and cures Cholera, Roup, Gapes, etc., as nothing else will. Makes bright red combs. Makes your chicks grow. Costs only One Cent a feed for 30 chickens. Mix it in the feed.
Saved His Chicks
My young chickens were dying. I had lost four dozen, when I bought a package Prussian Poultry Food, and gave it to the remaining ones in their feed. It saved them. I keep it on hand ever since.—C. R. RIGGIN, Latah, Wash.
It is a good egg producer and cheap to use.
Packages 25c and 50c. 25 lb. pail, 10,000 feeds, $3.50.

PRUSSIAN LICE KILLER
Kills Lice and Mites on Poultry
A liquid. You paint the perches and drop boards, or use with Sprayer. Lice and Mites can't exist where Prussian Lice Killer is used. It's the Best, Strongest and Cheapest, Goes further, lasts longer than any other. Hens can't feed lice and feed you.
Can't Get Along Without It
I am using the Prussian Lice Killer and could not possibly get along without it. It is the only thing I have ever used which will keep my poultry house and chickens from lice and mites. I have used other makes, but Prussian is the best. — FRED. FIESEL, Wilmington, Cal.
Prices, ½ gal, 50c. 1 gal., $1.00. 5 gal., $4.00

PRUSSIAN LICE POWDER
You Dust It Into the Feathers
Holding the chicken by the legs with the body hanging down, so the powder will get into the feathers and onto the skin where it will reach all the lice and mites. The
Prussian Lice Powder
does the work effectually.
Dust Setting Hens
with the Powder; also dust it into the nest when you set the hen; also dust the nest every ten days. The chicks will hatch free from
Lice and Mites
Vermin drives setting hens from the nests.
Packages 25c and 50c.

IS DEEP CULTIVATION AN INJURY TO AN ORCHARD.

(Continued from First Page.)

are thrifty, strong growing trees, bearing a good grade of fruit, while those which were receiving a surface treatment, and never plowing, are producing fruit which averages of a lower grade. Besides that, at the time the deep plowing was made, or rather, the summer season following, those same trees carried, safe and easy, six weeks on a rather coarse, sandy loam between irrigations, while other trees across the street, on fully as good soil, which had only the surface treatment would never carry above three weeks and even then showed heavy wilt between irrigations.

* * *

Uniform Supply of Moisture.—Of course, the moisture question is a great factor in this deep culture. The roots, prevented from feeding upon the warmer and richer surface soil, then seek the lower levels where the stored moisture from winter's rains is more uniform than can possibly be the condition in the surface soil which is subject to the immediate changes of temperature, dry winds, etc. We do not believe the lost fertility in the surface soil owing to this cutting of the roots can be a material factor in the condition of the tree. That is, if air, aiding nitrogen-forming bacteria to work upon the soil elements and in decomposing the minerals of the soil, accomplishes its result, the roots, despite any cutting off, will again seek those upper layers and utilize all of those elements, or, despite that, the percolating irrigating water would soon carry the fertility to the lower levels .

That this deep soil contains a more uniform supply of moisture, goes without saying. Of course, during a period of dry years it may be true that deep in the earth there is a drying out or loss of moisture which gives a dryer condition far below the surface than that of the surface with a reasonable degree of irrigation. But with proper care such conditions should not prevail and there should always be deep in the soil an abundant supply. Such being the case, roots induced to seek those levels and standing in this perpetual moisture are vastly better able to support the tree in trying times than are the surface feeders.

* * *

Utilize the Stored Fertility.—But, outside the moisture question is the other question of getting from the soil all the elements possible to support the tree. The study of commercial fertilizers and the theory of increasing the fertility of the surface soil is fascinating, but the settlement of bills where margins are ordinarily close are sometimes a reason for embarrassment. Therefore, with tons of the necessary elements in every acre of the soil, it behooves us to use every effort possible to induce the tree to use these native soil elements rather than to introduce them at considerable expense. That the surface soil contains more proportoinate fertility than the lower levels goes without saying but, at the same time, that the rootlets induced to grow in the lower levels secure much nourishment for the tree is well known.

One result of the deep rooting of the tree, thereby securing more uniform moisture conditions and more general utilization of the soil elements, will be, we believe, as it has been where thoroughly tried, a much more uniform and higher grade of fruit than has been the case in the shallower cultivation. It looks to reason that the regular and continuous growth and good condition of the tree will produce less puffy oranges, fruit of better texture and generally a much better product than will the intermittent tree which is every three or four weeks given a half sufficient irrigation.

The weather and crop conditions for the week ending July 3 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—Generally clear weather prevailed throughout the State during the week, with light fogs in the coast districts, and the temperature was somewhat below normal until Sunday. Higher temperatures prevailed in all sections at the close of the week.

Grain harvesting and threshing are progressing rapidly in all parts of the State and hay baling continues. The wheat crop is far below early estimates and is of poor quality in some sections ,but as a whole the yield is quite fair. Barley is yielding very good crop in nearly all sections, but oats are light. The hay crop is the best for several years in all parts of the State. Sugar beet harvest is in progress in Sonoma and Santa Barbara counties and the yield is considerably above average. Hops and beans are making fair progress and will be greatly benefited by the warmer weather; the present outlook is for about average crops. Corn, potatoes and vegetables are in good condition. Feed is drying, but is still plentiful and of good quality, and stock are doing well.

Fruit picking, drying, canning and shipping are in progress, and in many places the yields are better than expected a few weeks ago. The pear crop is much larger than estimated, and apricots, peaches and plums are very good. Prunes appear to be light in all sections, but may improve with favorable conditions. Apples give indications of a large yield. Grapes are advancing satisfactorily and there will be a very large crop. Citrus fruits and olives are doing well.

* * *

Eureka Summary.—Grain in some places is considerably damaged by aphis, but the crop is generally above average. Hay harvest is progressing; the crop is unusually heavy. High winds caused apples to drop; the yield will be a little below average.

* * *

Los Angeles Summary.—Hay stacking and baling are in progress on a crop ranging from light to extra good. Oats good to heavy; some rust. Oranges dropping somewhat. Walnuts backward but promising.

O. M. Morris is now on his way East where he expects to visit seed houses in the interest of a new seed house which he expects to open in Los Angeles during the coming fall. Mr. Morris has been connected with the seed business for some time and understands its various features, and he announces that he will have a thoroughly up-to-date seed house on the Coast

Hay put up in bales holds its sweetness and original juices much longer than when thrown loose into the barn loft. The farmer who feeds a large number of cattle or horses should own a baler; or hire a traveling outfit to put up his hay. Some hay presses are quite popular in districts when they have been used and proven rapid, accurate and economical. In a large number of sections East and West, the Alligator, Perpetual and Hercules Presses, made by J. A. Spencer, Dwight, Illinois, have become deservedly well known and popular.

THE JUBILEE ANNOUNCEMENT.

Californians interested in the poultry industry are more or less acquainted with the Jubilee Incubator Co., of Oakland, and their products. A few years ago the Jubilee incubators were made by dozens. Today they are made by hundreds and within a year they will be made by thousands and shipped to all parts of the world.

The new works will be located at Sunnyvale, Santa Clara county, where the company owns a tract along the line of the Southern Pacific which provided a frontage on the company's own switch of 780 feet. They will occupy their new quarters by August 1.

Another important department has been added—the poultry supply department. The company has decided to immediately establish the largest and best poultry supply house west of the Rocky Mountains, and will soon be manufacturing a full line of poultry foods and rations which will bear the Jubilee brand, a mark of quality and full value. The company has issued an announcement explaining in full their plans and it will be mailed to any address as requested. It is interesting and of genuine value. It will be sent, postpaid, to any address by writing to the Jubilee Incubator Co., Oakland, California.

IRRIGATION IN THE SACRAMENTO VALLEY.

The reclamation service has hopes of one of the greatest irrigation plans in the world for Sacramento valley. Hundreds of thousands of acres will be benefited. In a recent letter Mr. J. B. Lippincott, supervising engineer for California, said that the matter has attracted the attention of his department since 1895, daily records of the flow of the Sacramento river at Red Bluff have been kept, and the conclusion reached that the plan the government now has in mind to divert the waters of the river at Iron Canyon, four miles above Red Bluff, to reclaim, irrigate, and furnish electrical power for the Sacramento valley is the most important project now under consideration by the government.

Mr. Lippincott has directed his engineers to survey and map that section and says: "I believe the Sacramento valley offers the greatest undeveloped opportunity in arid America, and I also believe that the problem involved in the reclamation is one of the most intricate and extensive that we have to deal with. I believe it can be solved, and I hope the reclamation service will materially aid in its solution."

Field parties will soon be sent out to investigate reservoir sites in connection with the proposed dam.

Marry young. An old man's kiss is a poor excuse; it's just like apple sauce with too much juice.

Fresh doughnuts, mince pie and a man with a poor stomach is a combination that should not combine.

Los Angeles, Cal.

Queries and Suggestions

PERCHERONS.

Editor Cultivator: Will you tell me if there are any registered Percheron draft mares for sale on the coast?—H. C. J., Carpenteria.

There are some of the finset bred Percehrons on the coast. Francis I. Hodgkins, Stockton, California, will be able to supply information as to some of his fine stock. An article regarding his ranch and some of his stock, with illustrations of some of the premium winners appeared in this paper in the issue of May 26.

* * *

RHUBARB SEED.

Editor Cultivator: Can you tell me where to get Burbank's Crimson Winter rhubarb seed?—H. F. R., Hemet.

We do not know whether Mr. F. L. Hogue, of Carpenteria, still has a supply of the seed, but he recently advertised in the Cultivator that he would furnish at $1 per packet of 1000 seeds, which is sufficient to plant nearly half an acre.

* * *

MOVABLE FENCE.

Editor Cultivator: Will you kindly put me in the way of getting an idea of the best method of making movable hurdles or fence, to be used in keeping live stock, principally hogs, apart while grazing? Wish something to be inexpensive and at the same time effective. Would like information to be as explicit as possible.—Recent Arrival, Hollister.

Will any reader of the Cultivator who has information regarding the construction of cheap, movable fence favor our Hollister inquirer by writing to the Cultivator such information as they may have, giving explicit details, as far as possible, of construction? So far as we have heard, movable panel, made from wire mesh fencing, or the wire mesh stretched across field and staked occasionally, are the only suggestions which we have heard along this line.

* * *

SALT BUSH FOR POULTRY.

Editor Cultivator: I am anxious to get information regarding the Australian Salt Bush and its desirability as a poultry feed. What is best method of propagation? Does it grow quickly?—Recent Arrival, Hollister.

Of the salt bushes there are a vast number of different varieties, but the one usually referred to as the Australian Salt Bush and the one which has proved the most satisfactory as green food for poultry is the Australian salt bush, or Atriplex semibaccata. A native salt bush, Atriplex Brewerii, is spoken of in the gardening department by Mr. Braunton in this issue of the Cultivator. This has been given but little attention, however, and it is probable the securing of seed would be harder than that of the Australian salt bush, which is so common that all dealers can supply you with seed. Although spoken of as a "bush" it forms under favorable conditions for its development, large quantities of quite succulent forage which is readily eaten by either horses, cattle or sheep. It is much less woody than the common "sages."

It is a perennial and therefore does not require reseeding, except at long intervals, when it is pastured heavily it may run out. The seed may be sown at almost any season when there is sufficient moisture in the soil to germinate and maintain the seed until it secures a thorough foothold from the soil. This plant will stand a great deal of drought and also will grow and do well on soil of alkaline per cent enough to prevent any other plant securing a foothold. In fact, it has been said that no other forage plant so sturdily withstands black alkali. We have heard of cases where a plant has been planted in not very large quantity and allowed to arrive at good size before poultry was turned into the corral and within a very few days they had eaten it down to a mere stub. This proves the liking which poultry has for the plant.

One pound of seed will plant an acre, so that it is a most economical seed. Its habit of growth is very rapid, providing sufficient moisture be present. The value of the salt bush will be better appreciated when it is remembered that in the selection of foods the chief nutrients to be considered are the protein compounds or nitrogenous ingredients. They are indispensable to the healthy and vigorous growth of the animal body, for animals which have been deprived of all nitrogenous materials die in a very short time. That the salt bushes range high in these most important ingredients may be seen by the fact that it contains 2 3-4 per cent of protein, while alfalfa, which is especially high, has 4.91 per cent.

* * *

BUDDING ROSES.

Editor Cultivator:—Will you kindly inform me how to bud roses? I have an old copy of the Cultivator giving instructions how to bud trees. Will the same system answer?—J. M. B., Dos Palos.

The treatment is practically the same as to bud an orange tree, being sure to get a good bud from the desired scion and have the bush in healthy growing condition. The manner of cutting the bud and making the incision would be identically the same as for budding the orange tree.

* * *

HUMBOLDT COUNTY LANDS.

A subscriber in the San Joaquin valley recently requested information regarding lands and agricultural conditions in the coast counties north of San Francisco. We have written to George A. Kellogg, secretary of the Humboldt Chamber of Commerce, with offices at Eureka, and he replies as follows: There is considerable government land left in Humboldt county, but most of it is unfit for pre-emption. All of the best land was taken up long ago, and I could not advise any one to come here expecting to take up valuable land.

Improved lands, suitable for general farming purposes run in value from $50 to $300 per acre, according to quality and situation.

"Stump land" can be had in limited amounts for $5 to $25 per acre. Much of this is very good land, but it requires a great deal of work to put it in shape for growing crops.

More explicit information regarding the Humboldt section with illustrations and printed matter may be had by addressing Mr. Kellogg at Eureka. One point from pamphlet in question we note "Humboldt has the banner record for the production of oats and corn according to United States census reports. At the Chicago World's Fair wheat grown in the hills of Humboldt took first prize and showed the record yield per acre of 60 to 100 bushels." Of course, the great future of that country is dairying, of which it is the banner county of the State.

* * *

FERTILIZER FOR POTATOES.

Editor Cultivator: Will you please inform me if it will do to put fertilizer on the hills or rows of potatoes when planting? M. J. B., Hemet.

We do not think as a rule that fertilizer is applied to the hill when planting though we have heard of excellent results from using unleached wood ashes in the hills. It supplied the immediate potash necessary and was also found to be excellent in preventing the scab and the attacks by worms. But, by referring to the Cultivator of May 19th, you will note that Mr. Lobingier, who has had wide experience in California, recommends the use of nitrate of soda after the potatoes are well up; 100 pounds of nitrate per acre and fifteen or twenty days later, another 100 pounds.

Another authority recommends for Irish potatoes a complete fertilizer mixed in proportion of 500 pounds nitrate of soda, 300 pounds muriate potash and 1200 pounds superphosphate. Certain it is, the application of nitrate of soda to potato ground has given most beneficial results. The use of stable manure unless thoroughly rotted on potatoes has been condemned.

THE WOODBOX.

Settin' here tonight, I'm thinkin'
Of a home I ust to know;
Sort o' starts my heart a-sinkin',
That old scene of long ago,
In a kitchen I'm a-lookin',
In a farmhouse in a grove,
Past old mother there a-cookin',
Is the woodbox 'hind the stove.

Recollect it, don't you, mister?
You can see it same as me,
'Member how yer hands would blister
Now and then? And splinters, gee!'
See the chips and bark its holding?
Not a single stick of wood,
Hear old mother at you scoldin',
Tellin' you to fill it good.

Use to seem that box, you 'member,
Hardly gave you time to play,
Kep' you mad clean from September
Till warm weather came in May;
Seemed as though 'twould kill you, stil it
Didn't, now I'll tel you true;
Fer the chance I'd gladly fill it;
Yes, you bet, and you would too.
—Bide Dudley in Kansas City Star.

Sarah's Swains

Written for the Cultivator.

"Dear me!" exclaimed Sarah Miller, looking from the pantry window down the road at the tall lank figure coming towards the house. "If that ain't Bill Hawkins coming to see me, an' it's Friday evening, too."

She rattled the milk-pans around at a great rate, getting ready for Saturday's churning. She went to the opposite window to hang up her dish-cloth in the cool air when she happened to catch sight of another figure coming from the opposite direction.

"O, my!" she murmured, "an' there's Jim Daily—both coming to see me. There'll be some fun when they meet, I'll bet," and she laughed to herself.

Coming around the house to the front door, Bill Hawkins newly greased boots came to a sudden stop, and their owner stared dumb-founded at Jim Daily's plump figure just emerging from behind the rose-tree at the corner.

"Seems to me ye've made a mistake," Jim growled, nervously fingering his flaming necktie.

"Been makin' mistakes yerself, strikes me," answered Bill pulling at his torturing collar.

"Looky here, Jim," he said after a pause, "I've come on important business, an' you jest pull out, now, and come back again in about half an hour."

"If there's any pullin' out, you'll do it," said Mr. Daily, "I don't fix up an' come to see Sarah for nothin', either."

"Wal; then let's draw cuts who stays," suggested Mr. Hawkins.

"You draw, nuthin,'" answered Mr. Daily, "you jest git out o' this," and he took a step forward. At this Mr. Hawkins dexterously shed his coat. "You've been tryin' to cut me out fer a long time an' I—"

His words were cut short by the onrush of Mr. Daily, and the two crashed through the rose-bush and danced over the pansy-bed in front of the house. But this state of affairs was stopped as suddenly as it had begun.

"What do ye mean by this!" exclaimed pretty little Sarah, coming around the corner of the house.

"O, nuthin', me an' Bill was jest scufflin' roun' a little, jest a friendly wrastle, ye know," stammered Mr. Daily, trying to appear indifferent.

"O, yes!" exclaimed Sarah scornfully, "you both walk a mile to get to smash down ma's choice pansies in a friendy wrastle, didn't you? You know what I said the other time you fought about me in the peach orchard, now you can git!",

"I'm ready to 'pologize, Sarah," said Mr. Daily, "the fact is that Bill—"

"I don't want to hear a word from either of you," interrupted Sarah, "are you a goin' to git!" and she glanced angrily at them.

Mr. Daily darted one savage look at Mr. Hawkins, and turning on his heel ambled off up the road, while Mr. Hawkins shuffled off in the opposite direction. He tramped on for about a mile in silence, then he dropped wearily on a stump by the roadside. Finally he rose, "B'lieve I'll go back an' tell her I'm sorry. She was'nt so mad as she looked." So, retracing his steps, he once more rounded the corner of the house to halt dumb-founded at the sight of Mr. Daily's plump figure standing on tip-toe gazing in at the window between the shutters.

"Now, see here, Jim," Mr. Hawkins began, but Mr. Daily raised a warning and a beckoning hand.

"Sh-sh-sh! Jest take a squint in thar, Bill," he said. Mr. Hawkins looked in for a moment, then stepped back and stared down into the countenance of Mr. Daily. "Jim," he said, "I'm dry."

"So am I, Bill, lets go to the spring an' git a drink, then let's go to the store an' hev' a glass of beer. My! I hav'nt had a drop fer four months 'count o' Sarah bein' agin it!"

"That's my fix, Jim," remarked Mr. Hawkins.

Arm in arm the two sauntered through the orchard to the little spring back of the house, where they found seats and sat down to rest.

"Did—did he hev' his arm around her yet when you looked Bill?" asked Mr. Daily:

Mr. Hawkins nodded. "An' was a kissin' her right afore her ma, too," he added, mournfully.

"She was laughin' about us, too, Bill," said Mr. Daily, pathetically. "We don't stand no chance agin him nohow. Why, Arthur Crandall owns the biggest ranch around here, Bill," he added, looking into Mr. Hawkin's mournful face.

"Can't never trust a woman, nohow," remarked that individual, "now I'm goin' ter 'tend to business."

"That's me, too," said Mr. Daily rising to his feet.

"Where ye goin' to, now, Jim?" asked Mr. Hawkins, also rising. "To the store. Durn water for drinkin' purposes anyhow!" He linked his arm through Mr. Hawkins' and arm in arm the two slouched down the path together.—Selma Norman.

Don't cry because you're not pretty.

The Chaperon Speaks

Isabel accepted a cup of tea as though under protest, took a slice of lemon gloomily and hunted for the sugar tons with the air of one having a suppressed murder on her mind.

As she wore a most becoming new spring frock and her hair looked particularly well, being arranged in the latest fashion, I could think of no explanation of her gloom, inasmuch as she is generally vivacious and cheerful.

"It's so annoying to have to decide things," she snapped. "It upsets me so."

"Who is the man?" I asked, to help her along.

"How did you know it was a man?" she queried fretfully. "It might have been dress goods or summer hotels. You know how long I've known Peter Hendricks—three years—and I don't know this minute whether I want to marry him or not. And I've got to decide—he insists on an answer."

"How inconsiderate of him!" I said as she waited.

"There's every reason on earth why I should marry him," went on Isabel, fiercely. "He has position and education, and charming ways and a good disposition and loads of money, and I don't see why I don't know my own mind."

* * *

"You've got your problem mixed," I told her after an instant, during which she drank tea as though her life depended upon it. You're not worrying in the least over whether you're going to marry Peter. You know perfectly well you aren't. What you are trying to decide is whether or not you have the courage to marry Dick Bassett. Why waste time discussing Peter?"

Isabel leaned back in her chair and shut her eyes. She really looked worn out, and her attitude spelled dejection. "Maybe that's it," she admitted hopelessly.

I'll give it up," I told her. "I'm sure I don't know—and you don't seem to. Of course, it was foolish in you in the first place to pick out Dick Bassett to fall in love with. You should have said to yourself: "He's big and honest and good looking and a gentleman, and decidedly lovable, and the one man on earth for me, but with my bringing up and expensive tastes his $1800 a year settles him. It wouldn't buy my gowns alone.' You should have been practical, Isabel!"

"You don't believe a word you say," she flared out, her eyes very wide open. "It sounds horrid!"

"Don't I?" I asked, trying to look offended. "You don't fancy that I am foolish enough to preach love in a four-room flat to you, do you? It sounds beautiful in theory when the lovely young heiress deserts every habit of life she has been used to since birth, gives her Paris gowns to the poor and her jewels to feed the chickens and blithely dons a print dress in which to broil the beefsteak, and lives happily ever after. You couldn't keep your hands properly manicured."

"But if—if a girl really cares—that would help," Isabel said, rather protestingly, studying the ring. "I didn't dream you were so worldly in your views."

"Maybe it would help," I admitted, "if she were able to keep up on the Elysian Heights twenty-four hours in the day. But you know how it is now when you have all the material comforts of life. You get the blues and hate everybody. How would it be then? I'm surprised at you, Isabel. You've

been carted along on rose leaves always. You couldn't do it—you can't imagine how it would be. And you'd have to drop out of everything, for you couldn't keep up with your old crowd. No, on the whole, you'd better marry Peter!"

Isabel studied me shrewdly. Her mouth had been setting into firmer lines. "I wish I knew whether you were really in earnest or not," she said, wistfully. "About my not being able to make a success of marrying a poor man. Don't you think I could do it—if—if I cared for him—quite a good deal?"

"Poor, foolish child!" I said, enigmatically, with as wordlike a manner as I could assume.

I consider that one of the most tactful remarks of my whole career, for Isabel promptly chose to consider it a slur upon her heart, soul and mind, when she might just as easily have taken it to mean any of a dozen other things. She arose with dignity and gazed at me pityingly. "I suppose, with your views, you'll never understand why I did it," she said, "but I'm going to marry Dick Basset, manicured fingers or not!"

KEPT THEM BOTH AWAKE.

A clerical brother came in the other day to tell us a good story for publication "without names," says the Minneapolis Journal. It seems that in his congregation our clerical friend had two erring brothers who troubled him greatly by the habits they had acquired of catching a little repose during worship. Finally the pastor spoke after this wise to one of the wandering sheep:

"Brother Park, did you ever notice that Brother Benjamin had fallen into the habit of sleeping during service?"

Brother Park had not noticed it, but he was pained at the information.

"Well, might I ask you to sit beside him next Sabbath and nudge him in case he falls asleep?"

Brother Park would most certainly do so.

The clerical brother then seeks his esteemed co-worker in the vineyard, Brother Benjamin.

"Brother Benjamin, have you noted Brother Park's habit of sleeping during the sermon?"

Brother Benjamin had noticed it and had been pained.

"Well, would you do me the favor of sitting beside Brother Park next Sunday and nudging him in the case of drowsiness?"

Most certainly Brother Benjamin would do so.

The spectacle of the two good men keeping tab on each other in the sanctuary next Sabbath day nearly upset the dignity of our clerical friend during his ministrations.

NO CHANCE FOR HELP THERE.

A. B. Woods, the ornithologist of the Smithsonian Institute, returned recently from his vacation with an amusing story about a village usurer, says the Baltimore Herald.

"This usurer," said Mr. Woods, "had trumped up some iniquituous claim or other against a reputable widow. It was a claim that, if satisfied, would leave the widow altogether destitute, and she, on account of its injustice, disputed it. Therefore the usurer brought suit against her.

"The day before the trial the man visited his lawyer.

"What to you think of the prospects?" he asked.

"'Only fair,' said the lawyer, 'only fair. If you want a verdict in our favor you had better pray for it.'

"'Pray?" said the usurer, holding up his hands. 'Pray? No—no. God must hear nothing of this.'"

WERE ADAM AND EVE COLORED.

An American negro now in London gives a curious description of the origin of the colored race. He does not think that Adam and Eve were whites. Indeed, all people had dark skins until Abraham jumped into a pool of clear water one day. The darkness of his skin was removed by a miracle, and he emerged a white man. Others near him followed his example, with similar results, until the water gradually became brown. The people who then bathed became what are known now as Japanese and Chinese. Some lazy niggers were then about to jump into the water when Abraham ordered the caravan to move on and to this day they have remained black.

THE THEATER.

When you go to town to stay a few days and think you would like to go to the theater, don't go to the cheapest one, because you think you can't afford the best, but go to the best play and take the less expensive seats. I have seen a lot of the best things this winter from the gallery, where I was surprised I could see and hear so well—and as that was really all I went to the theater for I got so I looked down on the tops of people's heads without a twinge of envy. It's ever so much better to see a good play in a cheap seat than to see a cheap play from the best seat anybody could upholster.

THE ORIGIN OF A GREAT CHURCH

What we know as Methodism, or the Methodist Episcopal church, was in a crude way organized in 1739 by John Wesley in England. In 1743 he drew up the rules that have remained in practice until the present day. Notwithstanding the great results of his work in forming a separate Protestant denomination, John Wesley lived and died a clergyman of the Church of England.—The Earth.

WHAT IS "PROTESTANISM?"

The term "Protestants" was first applied to the followers of Martin Luther, because of their protesting against the decree passed by the Catholic States at the second Diet of Speyer in 1529. The term became the general designation for the system adopted by the Reformers in the sixteenth century and followed by their successors in later times. One of the tenets of the Protestants was that the authority of the Bible is supreme and above that of councils and bishops.

COULDN'T DECEIVE HIM.

"I want to get some bird seed," said the customer in the seed store.

"No, ye don't, smarty," replied the new clerk, recently acquired from the country, "ye can't joke me. Birds grow from eggs, not seeds."—Philadelphia Press.

"What are those purple posies down by the brook?" asks Gus. "If you mean," replies Clara, "those glorious masses of empurpled efflorescence that bloom in bosky dells and fringe the wimpling streamlets, they are Campanula rotundiflora."

Cookery Recipes

Dandelions.—Cut off the coarse, outer leaves, wash well, then leave in cold water for an hour to crisp. Drain, throw in a saucepan of boiling water that has been salted and simmer for twenty minutes or half an hour, if fully grown. Turn into a colander, press so as to extract all the liquor, then chop. Place a tablespoon of butter in a stew pan, and when melted add a tablespoon of flour. Add the greens, toss lightly with a wooden spoon and when the butter is absorbed, season with salt, pepper and nutmeg and moisten suitably with broth or gravy. Toss ten minutes longer, add if you like a tablespoon of cream, sweet or sour, and serve hot with a garnish of toast points or croutons.

* * *

Ragout of Veal Jardiniere.—A ragout is simply a palatable stew that is pleasing to the eye as well as the palate, instead of being merely irregular chunks of meat and potatoes with rags of onions thrown in. Have the butcher bone a breast of veal, roll and tie it; make a little veal suet very hot and brown the veal in this; cover with hot water, and when it has simmered one hour, add six small, young French carrots scraped and cut in halves; four stalks of celery cut in two-inch lengths, six small button onions and six small new potatoes cut in halves, and continue the cooking for another hour and a half. Dish the meat with the vegetables around, each pile by itself, alternated with little mounds of green peas, which have been cooked separately; strain the gravy, thicken slightly, and pour around or serve in a boat.

* * *

Berry Sherbert.—Mash half a gallon of strawberries or blackberries; add a gallon of water and the juice of two lemons; let stand four hours, strain, add one and one-half pounds of sugar; stir until dissolved, add ice and drink very cold.

* * *

Southern Negus.—Take one quart of red cherries, three pounds of blackheart cherries and four pounds of currants; mash and mix all together, and stand away in a cool place for three or four days; strain and boil the juice; to every pint add half a pound of sugar, let cool and bottle. Add two or three spoons to a glass of ice water.

There is no nicer spring breakfast than a sliced green pepper cut very small and cooked for ten minutes with two peeled and diced tomatoes in a little butter; add four eggs lightly beaten and stir as for a scramble

HOMELY HINTS.

Old loose kid gloves, worn when ironing, will save many callous places on one's hands.

A tablespoonful of turpentine to a pailful of water will help to set delicate colors in wash goods. It is also good for black wash goods as it keeps the black from becoming dingy. Add the turpentine to the rinse water. A tablespoonful of powdered borax in the rinse water will help to bleach white clothes.

Sponging the carpet with a strong solution of salt, or alum, or a weak solution of ammonia will brighten the colors and prevent moths.

To clean straw matting at housecleaning time, take it up as you would a carpet, spread it on the grass and sponge it off with warm water in which a large handful of salt has been dissolved.

Bright sunshine will remove scorch which has been made by using an overheated iron.

If the cover of a fruit jar sticks, do not attempt to wrench it off. Simply invert the jar and place the top in hot water for a minute. Then try it and you will find it turns easily.

Stains of varnish on the hands are sometimes very difficult to remove. As soon as possible, rub with a little alcohol on a soft rag; afterwards wash thoroughly in soap and water.

To Remove Ink From the Carpets.—As soon as it is spilled, throw salt on the spot, taking it up as soon as colored, repeating as long as the salt will show the ink, rubbing it in at the last, then sweep it out of the carpet. If rightly done, every trace of ink will be removed; have seen it tried with success on very fine as well as common carpets.

I remember, I remember, the fir trees dark and high,
I used to think their waving tops were close against the sky;
It was a childish ignorance but now 'tis little joy
To know I am farther off from heaven than when I was a boy.

CALIFORNIA SUGAR PINE.

Few users of wood know that on the Pacific Coast there is a vast quantity of lumber comparable in all essential qualities with the best grades of white pine ever produced in the East. This is furnished b ythe sugar pine, a tree commonly found along the western slopes of the Sierra Nevada mountains in California. Even when compared with the gian "big trees" with which it is often found, the sugar pine is not a puny tree, but often reaches a diameter of ten feet and a height of 250 feet. A single tree has been known to yield 54,000 board feet of lumber, and trees smaller than 18 inches are seldom cut at present. These facts make it evident that sugar pine lumber, in respect to the sizes furnished, is far beyond the Eastern white pine—even the pumpkin pine o fearly days.

The wood is scarcely distinguishable from white pine. It is practically of the same weight and the same color. It is somewhat more resinous, however, and perhaps a little brasher. It is soft, straight-grained and easily worked. It is used for everything for which white pine is available, and is especially valuable for pattern work. The wood is already finding its way into the eastern markets and while it is not at all likely that anything but the best grades can be shipped long distances, there is no doubt that sugar pine lumber will more and more replace its eastern relative. There is no difficulty whatever in furnishing plank up to four feet in width and absolutely free from defect, at a price that is low for material of that quality.

The cut of sugar pine lumber in Californian has increased from 55,000,000 board feet in 1900 to 120,000,000 feet in 1904, and it is estimated that there are 25,000,000,000 feet of it still standing.

Sugar pine does not form extensive forests by itself, as the white pine of the East once did, but grows with western yellow pine, white fir, incense cedar, and the "big trees." In Northern California it is found at altitudes between 2,000 and 6,000 feet above the sea, and in Southern California at altitudes between 5,000 and 10,000 feet.

The tree produces a large quantity of seeds in cones that often are twenty inches long. The seeds are large and edible, and consequently are sought by squirrels and other animals. The Indians also gather them to eat. On this account, and because the seedlings are easily killed during the first five years by lack of moisture or proper shade, the sugar pine does not reproduce itself readily; but the lumber is so valuable that there is every reason why an effort should be made to replace the trees that are cut down by others of the same kind.

WHAT A BOY CAN DO.

Be frank.
Be polite.
Be prompt.
Be obliging.
Obey his parents.
Keep himself tidy.
Keep out of bad company.
Never laugh at a coarse joke.
Never be disrespectful to old age.
Be kind to his brothers and sisters.
Take the part of those who are ill used.
Never make fun of another because he is poor.
Never tell or listen to a story which he would not repeat to his mother.

Eastern, New York Cream ....15@16

EGGS.

Offerings of eggs have been very liberal, with the result of slightly shading of quotations.

EGGS—Per doz.:

Ranch, selected large .....18@20
Ranch, good to fancy .....17@18
Store .....16@17
Eastern, firsts .....16@18
Eastern, seconds .....15@16

POULTRY.

POULTRY—Hens, $3.50@4 per dozen, with fancy large at $5@5.50; Broilers, $1.75@2.25 for small and $2.50@3 for large; Fryers, $3.50@4; Roosters, $4@4.50 for old and $5.50@6.50 for young; Geese, $1.50@1.75 per pair; Goslings, $1.50@1.75; Ducks, $3.50@$4.50 per dozen for old, $3.50@4.50 for young; Pigeons, $1.25@1.50 per dozen for old and $1.50@1.75 for young; Live Turkeys, 18@20c per lb for Hens and 19@21c for Gobblers.

FRESH FRUITS.

Watermelons are the latest favorite in the fruit market, two to four carloads per day being received. Warmer weather is helping to move the fruit at very satisfactory prices. Strawberries are weak, being of poor quality, many of them being sunburnt. Apples are increasing in quantity and high grade yellow peaches are also more freely offered.

Strawberries, $2@4 per chest for Longworths, large varities $2.50@3.50 for Watsonville and $2.50@4 for Santa Clara.

Loganberries—$2.50@3.50 per chest; Blackberries, $2@4.

Huckleberries—10c per lb.

Raspberries—$2.50@4 per chest.

Currants—$4@5 per chest.

Apples—40c@$1.25 per box for current offerings. Crabapples, small boxes 50c.

Apricots—30@60c for small boxes and crates; baskets, 12½@25c.

Plums and Prunes—Small boxes and crates, 25@65c; basket Plums and Prunes, 12½@30c.

Peaches—40@65c for small boxes; large boxes, 65@$1.25; carriers, 65@75c; baskets, 40@60c.

Pears—50@75c per box, for Dearborn Seedlings; No. 1 Bartletts, $2.

Figs—Black, 35@50c for small packages and 75c@$1 for large boxes.

Grapes—$1@1.25 per box for seedless and $1.25 for black.

Cantaloupes—50c per crate for specials. $1.50@1.75 for ponies and $2@$2.50 for standard.

Watermelons—1½@2c per lb., or $2@$2.50 per dozen.

VEGETABLES.

Liberal offerings of potatoes have been made which have teuded to materially weaken the market. Onions are in light supply aud very firm.

POTATOES—New crop, in sacks, 40@75c per ctl.; 50c@$1 for White; Garnet Chile, 70@80c.

ONIONS—New Red, 35@75c per sack; Yellow, $1.25 per ctl.

VEGETABLES—String and Wax Beans, 1½@3c per lb.; Tomatoes, $1.50 @2; small boxes and crates, $2.50@ $3.50 for large boxes, and $1.40@1.50 per crate for Mississippi; Green Peppers, 8@12½c per lb; Green Peas. $1@1.75 per sk; Asparagus, 4@7c per lb; Cucumbers, 25@35c for small boxes and 75c@$1.25 for large; Summer Squash, 25@50c; Egyptian, 5@8c per lb; Green Corn, 50c@$1.25 per sk and $1.25@1.75 per crate.

Fruits; Dried.

New crop prunes are so far held on the .03 basis.

DRIED FRUITS—Prices for carload lots, f. o. b. at California common shipping points, in bags, for 1904 crop, are per lb as follows:

Apples—Evaporated, 4½@7c; Sun Dried, nominal.

Peaches—Fancy, 9½c; choice, 8½@ 9c; standard, 8¼@8½c; peeled, 15@ 18c.

Plums—Pitted, 6@8½c, as to quality.

Silver Prunes—4½@8c, as to quality.

Prunes—Sack basis, f. o. b.: For boxed goods add ¼@½c; 30 to 40s, 5½ @6½c; 40s to 50s, 4@4½c; 50s to 60s, 2⅞c; 60s to 70s, 2⅜c; 70s to 80s, 2@ 2¼c; 80s to 90s, 1⅞c; 90s to 100s, 1¾c; 100s to 120s, 1½c.

Nectarines—White, 7½@8½c.

Pears—Bartlett, unpeeled, halves, fancy, 10½@11c; choice, 8½@9c; standard, 7@7½c.

Figs—White, 2¾@3¼c; Black, 2½ @5½c.

RAISINS—Prices, per lb., f. o. b., Fresno, are as follows: 1904 crop—Clusters and layers, 20-lb boxes, fancy, 4-crown, $1.35@1.40; London Layers, 3-crown, 90@95c; do, 2-crown, 85 @90c; loose Muscatels, 50-lb. boxes or bags, standard, 4-crown, 4½@5c; do, 3-crown, 4@4½c; do, 2-crown, 3@ 3¼c. Seeded—Per pkg, fancy, 16 oz, 6c; do, 12 oz., 4⅞c; choice, 16 oz, 5c; do, 12 oz., 4⅛c; fancy, bulk, per lb., 5¾c; choice, 4¾c; Thompson Seedless, 50-lb. boxes, unbleached, 4¼@ 4½c; Seedless Sultanas, unbleached, 2¾@3c; Seedless, 2@2½c.

Honey

HONEY—New crop, Comb, per lb., 10@11c; Extracted Water White, 6@ 6½c; Light Amber, 5@5½c; Dark Amber, 4@4½c.

BEESWAX—Per lb., 28@29c.

HOPS.

The price of desirable stock is 24@ 27½c per lb., according to quality.

BEANS AND PEAS.

BEANS—Prices, per ctl. for sound selections: Large White, $2.50@2.90; small do., $3.25@3.50; Pea, $3@3.25; Limas, $5.75@5.90; Red, 6½@8c; Pink, fancy, $3.65@3.90; recleaned, ordinary to choice, $1.65@2.35; Bayos, $3.65 @3.90; Blackeyes, $3@3.10; Red Kidneys, $4.50@5. Rain-damaged lots of all descriptions offering from 50c@$2 a ctl below foregoing figures, according to condition.

DRIED PEAS—Prices per ctl: Niles, $2.50@3; Green Peas, $2.50@2.75; Field, $2.40@2.65.

SEEDS—Prices per ctl: Yellow Mustard, $3@3.25; Trieste, $5@5.20; Canary, imported, $6@6.50; Hemp, $3 @3.50; Flax, $2.10@2.30; Rape, $2@ 2.50; Timothy, $4.75@5.25; Alfalfa, California, $9@11; do, Utah, $12@18.

LIVE STOCK MARKETS.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5¼c; second quality, 4¾c; third quality, 4¼c; thin Cows and Heifers, 3@4c; Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent shrinkage.

CALVES.—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy, 3@3½c, gross weight.

SHEEP—Per lb. Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¾@5¼c per lb, live weight.

OATS—Good to choice, White, $1.75 @1.80; Red, $1.70; Black, $1.52½@ $1.55.

BARLEY—Choice, No. 1 Feed, 92½ @95c; off grades, 87½ @ 90c; Shipping and Brewing, nominal; Chevalier, nominal.

CORN—Good to choice, per ctl: California, new, large yellow, $1.40@1.45; small do, $1.50@1.55; White, $1.40@ 1.45; Eastern, yellow, $1.37½@1.42½; White, $1.40@1.43¾; mixed, $1.35@ 1.37½.

RYE—Good to choice, per ctl., nominal at $1.70@1.75.

CITRUS MARKETS

Los Angeles, Cal., July 6, 1905.

The market during the past week has sagged a little on account of the demand for Fourth of July trade being over. Auction markets showing some weakness, although extra fancy stock in good condition continues to bring high prices. The Western markets are in fair condition and beginning to send in orders for shipment of Valencias for the regular trade. The sag in prices was caused by shipments continuing a little too heavy from the 20th to the 30th of June, arriving too late for the Fourth of July trade. The limited shipments that have been going out the last week will have a tendency to bring up the markets in good shape and with the light holdings of Valencias in the country there seems little reason for anything but satisfactory prices, if the shipments are properly regulated.

The Lemon market in the West has been rather sluggish on account of the cool weather, with prices from 25c to 50c per box lower, although the auction market on foreign stock remains about the same. The sale of a very small cargo showing an advance this week. Shipments continue to go out quite heavily, and while the situation will probably cause somewhat lower prices in Western markets, there is no reason why fair prices should not prevail, as California lemons may at present be sold anywhere in the United States from here to Boston.

NEW YORK.

Total number of cars sold at auction during last week was 71 as against 65 for prior week. Market on Navels was exceedingly weak, owing to very heavy decay and low grade of stuff shipped in. Where assurance was felt that fruit would show a small decay. Navels commanded fancy prices, running as high as $5, but the bulk of the sales were far below that. Valencias held very strong during the entire week, commanding an average of from $2.05 to $4.25, fancy Navels $3.75 to $5; choice, $2.30 to $2.90; Standards commanded $2.50 to $2.75.

Lemons showed very fair during the week, though there was a decline in price which ranged from $2.15 to $3.50.

Nine cars sold at Monday's auction.

Quotations on Valencias were: La Mesa, xf, Riv Ex, $3.95; Arbutus, st, CCU, Highland, $3.30; Carnation, xc, CCU, Riverside, $3.55; Cactus, xc, CCU Highland, $3.70; Golden Eagle, st, C. C. Chapman, $3.50; Independent, fy, Highland, $4.25.

Mikes, $3 to $3.80; Sweets, $2.70 to $3.25; Lemons, $2.20 to $4.05.

PITTSBURG.

Four cars sold at auction on Monday.

Some quotations were: Cal. Sunshine, fy, Redlands, $3.40; Golden Orchard, $3.25.

Mikes sold from $3 to $3.25; Sweets $1.75 to $2.95; Navels went to pieces owing to condition and sold from $1.30 to $1.55.

NEW YORK.

Wednesday's auction was very quiet with few sales. Navels in bad condition. Best fruit is now being secured from cold storage. One of best selling shipments of Navels was a car of Australians. Valencias are favorites and show best of keeping qualities.

Lemons are firm with no material change in the market.

A total of 13 cars was sold.

Some sales: Valencias. Loma Vista, ch, Redlands, $4.25; Ind. fy, Highland, $4.05; Old Mission, fy, C. C. Chapman, $4.85; Clover, xc, R O G Assn, Redlands, $3.15; Bear, xf, O-C Ex, Upland, $3.95; Carnation, xc, CCU, High Grove, $3.50.

Navels, $2 to $3; Mikes, $2.15@ 4.45; Lemons, $2.65@3.70.

BOSTON.

Twelve cars on Wednesday. Market strong and active on all sound fruit. Even the poorer keeping Navels sold quickly.

Valencias brought: Bear, xf, O-C Ex, $4.40; Rey, fy, S T Ex, $3.15; Fiesta, xc, Riverside Ex, $3.10; Blossom, xc, CCU, Redlands, 3.10; Golden Rod, ch, CCU, Allessandro, $3.80; Camellia, xf, CCU, Redlands, $4.10; Perfection, fy, CCU, Allessandro, $4.20.

Lemons, $3 to $3.75; Mikes, $1.20 to $3.30; Sweets, $2 to $3.05.

PHILADELPHIA.

Wednesday's auction took 13 cars.

Some quotations: Eagle Head, xf, I. L. Lyons & Son, $4; Pointer, xc, A. C. G. Ex, $4.15; Tiger, fy, S B Co Ex, $3.55; Independent, ch, Highland, $3.40; Golden Fruit, fy, G. O. A., $3.85.

PITTSBURG.

Five cars sold Wednesday.

Navels sold $1.30 to $1.50; Sweets, $3.10; Mikes, $1.15 to $1.55.

SAN FRANCISCO.

Condition of citrus market largely nominal.

Navels, largely nominal; Valencias, $3@3.75 per box; Mandarin, small boxes, $1.25@1.50.

Lemons—75c@$3 per box; Limes, Mexican, $4@4.50; Grape Fruit, $1.25 @2.50.

CITRUS SHIPMENTS.

Citrus shipments since November 1 total 27,200, of which 3023 were lemons.

The testimony of Mr. Brown of Redlands, before the Inter-State Commerce Commission in which he stated that it was his opinion that the icing charges were perfectly satisfactory to him and to the fruit growers whom he represented, has created somewhat of a storm amongst various fruit growers, some of whom he (mis)represented. A writer from Redlands informs us that the Board of Trade of that city had a very stormy session over the matter and correspondents of the daily press speak of a meeting at Colton which may be characterized as a warm number.

One of the statements in the resolution passed at that time is, "Whereas, Mr. Brown's interest in the citrus industry appears to be one-sixth share of ten acres, equal to about 165 orange trees, it is quite evident that he represents about the same proportion of the orchards as his testimony represents sentiment of the orange growers." The resolution further declares that the citrus-fruit industry must have relief by the reduction of freight and icing charges and that those charges should be placed in the hands of the Inter-State Commerce Commission.

"Where'd you get that red nose?" snorted Mrs. Bilkington. "Out of a bottle. Huh!"

"Where'd you get those red cheeks?" retorted Mr. Bilkington. "Out of a box. Huh!"—Houston Chronicle.

INDEPENDENT IRRIGATION

By far the largest portion of the irrigation of this State is where the gravity flow of the water to the land supplies the cheapest known means of securing water. There are cases, however, where possibilities of soil and climate combine to give high value to the product and where the gravity flow may not be secured, or, where it is insufficient. In such cases the deep well or the centrifugal pump have come in and given vastly increased value to the output.

There have been cases where the season's cost per acre for water has been greater than the total cost of improved land per acre in most sections of the Middle West.

Our government appreciates this great benefit to arid America, as is shown by its plans for the expenditure of over $27,000,000 in irrigation systems. We take pride in referring to these great works and in giving illustrations of them, but the more modest deep well and centrifugal pump have a mission which means much to all sections, and have added greatly to the wealth of the State.

The centrifugal has been a success many years, but the use of the deep well to lift larger quantities of water is a California invention. Here it has been perfected as in no other place in the world.

We give on this page an illustration of one of the most successful of these pumps.

... COULSON'S SPECIAL MOULTING FEED ...

A FEATHER GROWING FEED

A specally prepared or properly balanced mixed feed containing the right component parts of materials for producing the rapid growth of feathers.

The term "molting" denotes the process of the birds shedding their old feathers and growing new plumage.

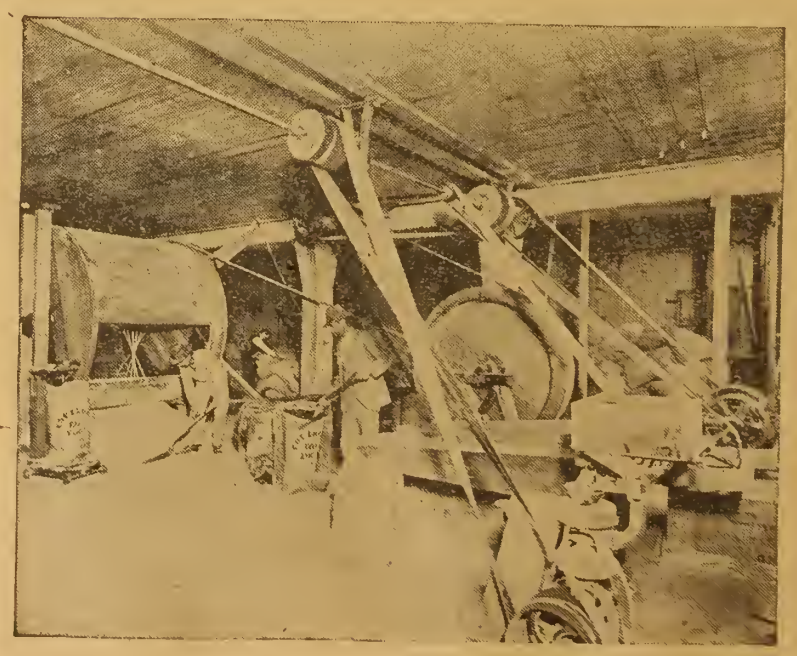
It is not necessary to starve the hens to make them molt, neither is it necessary to stop egg production. Hens fed with good feed and with good digestive capacity, can lay eggs and make feathers at the same time.

Keep hens for profit—intelligent feeding returns a profit. Feed a good balanced ration (Coulson's Egg Food) the year round so as to keep the fowls in good normal and healthy condition; then when the molting season comes and you want your fowls to molt, and get through molting before winter sets in, just start feeding them COULSON'S SPECIAL MOLTING FEED, and the fowls wil soon be getting a beautiful glossy plumage (due to articles in the feed) and will get their new feathers in short order; for in this Special Molting Feed they get the material needed for feather production.

Knowledge is power, and the knowledge needed now by poultrymen is to know just what foods contain the most of certain kinds of nutriments, and will produce the rapid growth of feathers and also keep the bodily health of the fowls. This is why it pays to feed Coulson's Special Molting Feed during the molting season.

Young healthy fowls fed on the right kind of feed will complete their molt in sixty days; older fowls will take longer. Birds not properly fed during the year will be weak during the molting season; they lack vitality, and will molt very slow, probably taking six or more months to get their new growth of plumage, and quite a number of the weaker birds die from the strain of molting or from exposure.

Loading Cars with Coulson's Food for Laying Hens



Interior Scene of Coulson Co. Manufactory

Young birds will molt and grow new plumage at the expense of health; old fowls will keep up their bodily needs, and go bare unless they are furnished the proper food to make the feathers grow.

The molt is a strain on the vitality of any fowl, for besides keeping up the heat and wear and tear of the body, the fowl must produce and grow new feathers; consequently the fowls should be fed a good rich food containing the right compoment parts of ingredients that will make feathers, and unless fowls are kept in good healthy condition, and fed the right food, many fowls will die during the molting season.

When fowls have been fed the year around one meal a day of Coulson's Egg Food so that they are in fine health at the beginning of the molt, if they are fed then for two months on Coulson's Special Molting Food, the growth of new plumage will be rapid, the new feathers appearing gradually as the old feathers drop off; and the bird may never appear worse than a little rough coated, and the egg production will average about one in three days. Some birds even doing better, according to their digestive capacity.

Any one keeping fowls will surely be pleased to get eggs in fall and winter when eggs are bringing the highest prices. For this reason one should assist the fowls during the molting season by feeding them Coulson's Special Molting Feed, so that the fowls will get through the molt before the winter weather sets in. The fancier also desires his fowls to complete their molt early so they will be in exhibiting condition for the poultry shows.

Fowls fed on Coulson's Special Molting Feed will have a beautiful bright, glossy plumage (a condition of perfect health), and will be pleasing to the eye, so that the owners will be proud of their birds. This feed supplies the fowls with the minerals and protein substance, etc., needed for the growth, so that fowls can complete their molt and begin laying before winter.

Pajaro Valley, Its Great Apple Industry

Importance of the industry to a State, by President C. H. Rodgers of the Apple Crowers Association

There is an old Indian tradition that at a remote period the mountains were continuous across what is now the entrance to San Francisco bay and prior to the time that an earthquake rent the mountain and formed the Golden Gate, all the drainage waters from the great central valley of our State met the ocean in what is now Pajaro Valley.

Modern scientific research confirms the legend as correct. Furthermore, it is obvious to anyone familiar with the topography of the region that were a barrier thrown across Golden Gate today the waste waters of the interior would first accumulate, forming an immense lake covering over the territory now included in San Francisco bay and Santa Clara valley, finally being able to reach the ocean only through Pajaro valley.

Assuming the legend a fact, the great depth of soil of this valley and its remarkable fertility might be accounted for in that they are the concentration of richness carried down through countless ages in suspension and solution by the flood waters from the slopes and valleys of the Sacramento and San Joaquin rivers and caused to precipitate on meeting the waters of the ocean.

* * *

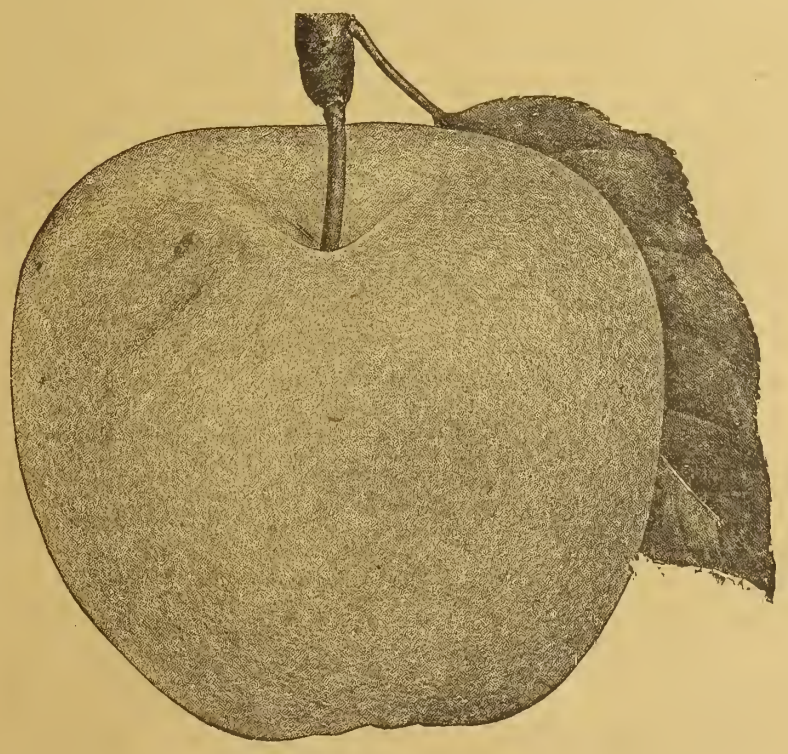
Pajaro—Bird—The valley was discovered in October, 1769 by the Portola expedition, which, under instructions from the king of Spain, had been sent north by land from San Diego in search of Monterey Bay. After the long, tiresome march over desert and parched soil, so pleasing was the contrast between the scene spread before the little company of explorers on first viewing the valley compared with that region which they had recently traversed, the scribe of the expedition in his records gives expression to his admiration in these words: "A meadow beautiful to behold, because of the great variety of trees and plants." The locality received its name on that occasion. Pajaro means "bird" in the Spanish language and the name was certainly appropriately applied, for in no other locality could be found the great number and variety of birds.

* * *

Extent.—The valley extends east and west and opens out upon Monterey bay midway between the cities of Santa Cruz and Monterey. It is surrounded on the north and east by the Santa Cruz mountains, which divide it from the famous Santa Clara valley and on the south a low range of hills divides it from the extensive Salinas valley in Monterey county.

Though limited in area, being only ten miles long by about four wide, its favorable combination of climate and soil make it specially fitted for the production of the greatest variety of crops.

With an average rainfall of over 20 inches, an exceptionally fertile soil extending to the water-table, which latter varies from eight to twenty feet from the surface, mild winter temperature



and summers cooled and moistened through ocean influences, where else from an agricultural standpoint, can a more ideal spot be found?

* * *

Variety of Products.—While the apple crop is first in importance, the list of products covers the widest range, including all the deciduous tree fruits—the apricot, cherry, prune, plum, peach and pear, all varieties of berries, all the cereals, hay, potatoes, sugar beets, beans, corn, alfalfa, hops, squashes, melons, garden "truck," nuts, dairy and poultry products, the latter particularly, are assuming important proportions. Then, too, the nooks in the bordering mountains make a very creditable showing in grapes, lemons and oranges.

Irrigation is not necessary except for berries.

The revenue realized from these industries has caused this community to become one of the most prosperous. It is a busy place, with employment for all its inhabitants and all who will, even the most humble, may have a bank account.

Individual holdings are small, varying generally from ten to seventy-five acres. So well contented are land owners with their profits that it is seldom a change of ownership occurs in best lands and when transfers are made, the price per acre reaches into the hundreds. Though as stated the best lands are difficult to obtain even at high prices, yet very good lands may be bought in the foothills at seventy-five dollars and upwards, per acre.

Watsonville, the only town, is centrally located. Its population is upwards of 4000. Here is the concentrating point for the products of the surrounding region and also the distributing center of the valley and territory adjacent thereto.

The continual inflow of some of the already enumerated products during every month of the year, with ready sale or exchange for other commodities, makes Watsonville one of the liviest and most thriving towns on the coast.

Shipping facilities are good, there being three lines competing for the traffic. There are the S. P. Coast Line, which passes through the valley, the Pajaro Valley railroad, and the Watsonville Transportation Co., an electric and steamship line owned by the citizens.

The building of the last named transportation line was the result of what our people considered unjust discrimination on the part of the S. P. R. R. Co., against this locality. Becoming exasperated after repeated petitions to the railroad authorities for relief, and as often being refused, the people of the community in 1904, through sale of stock and bonds, raised funds, built an electric road to Monterey bay, five miles distant from Watsonville, there connecting with our own steamer.

The inauguration of this new system brought about a revolution in conditions pertaining to the local freight traffic. Not only were rates reduced, but other matters which had caused shippers much unnecessary annoyance and loss, were speedily remedied.

The existence of this, the people's traffic line, though at present somewhat embarrassed financially, not only inspires producers and shippers with a feeling of independence, but also presents great possibilities for the future welfare of this locality. With the Isthmian canal completed, our products, chiefly our apples, which must find sale in distant markets, may be sent by ship-load from Port Watsonville direct to any seaport market of the world. In that event the cost of transportation would be materialy reduced and the net profit on the product proportionately increased.

* * *

Apple First.—In almost every new settlement since the founding of our country, the planting of the family orchard followed close after the building of the home. Pajaro was no exception to the rule, as we find that an orchard was planted as early as 1853, shortly after the first American settler located here. In those early plantings, the apple generally had first place. This proved the case here, also, and the early settler in selecting his trees for the family orchard aimed generally to secure a great variety of apples. This was a wise procedure, as there was not other means of determining what varieties were best adapted to the locality and the results of the tests proved of value in planting later years.

* * *

Best Varieties.—Though all the known varieties can be produced in the Pajaro district, all do not attain a high standard of excellence, and some prove a disappointment. Summer

(Continued on Page 42)

SUMMER PRUNING.

From careful experiments made by the Horticultural Department of the Kansas Experiment Station during the past four years it seems that the pruning of fruit, shade and timber trees during the early summer and late spring is more satisfactory and secures better results than pruning done during the dormant season—winter and early spring.

Wounds made before the middle of July have healed rather more quickly than have those made at a later date, but wounds made as late as August 15 have healed very successfully. The danger of loss of sap is less after the tree is well in leaf than from wounds made during winter and spring.

In extensive tests made on an apple orchard some very satisfactory results have been secured with ten-year-old trees which had borne but little and showed but few fruit spurs. Trees pruned in the summer of 1902—the pruning consisting of cutting back new wood and thinning out where a heavy growth shaded the two and three-year-old wood—and a similar but lighter pruning given in the summer of 1903, were full of bloom in 1905 and are carrying a very fair crop of fruit.

Trees pruned in summer have grown fewer "water-sprouts" than those of similar age and grown in a similar soil, pruned in winter or early spring. Water-sprouts removed during summer are less liable to be followed by another crop of the same growth than where the pruning is done in winter.

The operator is less likely to remove a large amount of wood, for he can readily see the danger of sun-scald where too many or too large branches are removed. The thinning out and cutting back of the younger branches should be all that is required when the orchard has had a reasonable amount of care given to its formation, and this light pruning given in early summer seems to be good treatment for unproductive trees.

SPRAYING FOR MOTH.

The Watsonville Pajaronian, referring to Horticultural Commissioner Rodgers' spraying operations this year says that he is using entirely arsenate of lead and is much pleased with the results.

He says that it is a difficult matter to find a worm on the sprayed trees, while check trees in the same orchard show a number of the pests. While it is too early in the season to proclaim victory over this dreaded pest, Mr. Rodgers firmly believes that in the arsenate of lead orchardists of Pajaro valley have a remedy that will prove effectual in the case of the codling moth.

It is reported that the moth is showing up in greater numbers than ever before and that the growers who neglect to spray will be able to get only a small percentage of their fruit into the higher grades. Every step should be taken to secure from the bountiful crop which is promised for this year as much increase as possible and this can only be done by well graded fruit, free from worms.

WATERMELONS.

California orange growers are not the only ones who are anxious to dispose of their fruit crop to the early customer to the extent of shipping green and sour fruit, for word now comes through the Chicago Packer that Georgia and Florida watermelon growers are shipping to eastern markets some fruit which is entirely unfit for eating. The commission men, to overcome this, hold the fruit to ripen until it has lost its best quality and this has resulted in serious injury to the watermelon trade. The Packer also announces that the usual eastern market wants no small melons and says to ship nothing under twenty-five pounds.

There is on foot an effort to spread the field of growth of the Rocky Ford melon in many sections of the South, in order to fill the early markets from those sections. The first of these melons arrived in Cincinnati market this year on May 25th.

The cool weather of Chicago has seriously affected the market at all points, causing exceedingly slow sales of watermelons. The quality of the stock has been very high as a rule, twenty-five pounds being an average size. Such fruit has been moving at about $150 a car, running about 1000 to 1100 melons per car.

THIN THE APPLES.

How can quality be secured? By growing only high grade apples, and not more to the tree than each tree can easily carry; by marketing only the choicest apples, not smaller than four-tier stock, wrapped, packed and boxed as the trade requires.

This is a good time to work together to regain first position for Pajaro valley apples. The season has been most favorable for the trees and growing fruit. Supplement the work of nature by taking off the surplus and scarred apples on each tree until not smaller than four-tiered stock is assured. Then let the apples properly mature, and grade to right color and pack properly when they are picked and matured. If this is done we need have no fear of the competition of any Newtown or Bellflower district in the country, for our apples will sell readily and at right prices.

Don't forget to thin—and then thin again, and then some more.—Pajaronian.

The annual meeting of the American pomological society occurs at Kansas City, August 8 to 10. The most prominent horticulturists of the United States will be in attendance. This society is closely connected with the department of pomology at Washington. L. A. Goodman, 4000 Warwick avenue, Kansas City, Mo., will furnish further information.

Don't make the same mistake twice.

VITALITY OF WEED SEEDS.

An interesting light has been thrown upon the subject of validity in weed seeds by Prof. W. J. Beal, in the Michigan farmer. "In the fall of 1879," he says, "twenty-two years ago, I selected seeds of twenty-one kinds of plants, all of them common weeds except one. A considerable number of sets of these were buried in 'clean dirt,' consisting of sand from a depth of about two feet. Fifty seeds of each kind were counted out and placed in each bottle which was buried at a depth of two feet. The seeds were well mixed in each bottle with the sand referred to. At periods of five years a set has been dug up and tested. At the expiration of twenty years, i. e., two years ago this fall, one set was taken out and the sand containing the seeds placed in two soup plates and gently watered. Some seeds were prompt in coming up, and were removed and tallied as they were identified. But there were laggards which skulked in the moist sand. I dried off the dirt for a rest from time to time, and on wetting the sand after two two weeks to a month or more other seedlings appeared. The last long rest consisted of perhaps eight months, continuing until November 15, 1901. After five days three seedlings are already in sight and I am expecting others after a little more time. As I look at it, the delay of some seeds in germination is of great advantage to the weed, for, if a great many seedlings start, there may be too many to thrive well, and some will be choked and perish. Again, some of the seedlings, or all of them, may be killed by an untimely frost or by the ruthless hand of the tidy farmer and when the ground is stirred there is a reserve of seeds to start another crop as a second planting, and still others may serve as a third or fourth planting. In case all the seeds were favorably exposed when fresh, most of them, probably all, would germinate. After they had been buried twenty years or more a variable number of seedlings appeared of the following species: Our most common prickly pig weed, mustard, shepherd's purse, pepper grass, mayweed, common mallow, evening primrose, smartweed, purslane, narrow leaved dock, a chickweed, the blanket-leaf mullein—twelve in all out of the twenty-one species buried. If any additional lesson were needed regarding the cost of growing a crop of weeds—of permitting weeds to get a start—here it is. If the earth is once well seeded and a man begins at once to keep each weed from going to seed, he will not kill the last seedling of the old crop inside of twenty years or more."

The world is willing to take off its hat to the boy or girl who works.

GOOD APPLE YEAR.

Three thousand carloads of apples is the estimate of the output of the coming crop of the Pajaro valley. It is said that handling of this crop will test to the fullest capacity the packing houses of the valley. It is hoped the cars will average at least $500 for all varieties, which will make a neat little addition to the bank account of Watsonville when a million and a half is secured at the end of the season. The price may, however, have a serious handicap in the fact that last year's output of almost the entire valley was really below its former good quality. The cause of this is said to be a hot wave which swept over the valley during the critical time in the growth of the fruit, seriously injuring it in texture and flavor. This may be remembered by the trade but, at the same time, we believe once the good quality of this year's fruit is apparent, the trade will be quick to appreciate it and it wil sell upon its merits of the present year. The Pajaronian makes an appeal to the growers and packers to see that none but the finest fruit, properly sorted, graded and packed, reaches the markets.

SOME HONEY PRODUCED IN CALIFORNIA.

From an address made by Mr. C. H. Clayton before the Committee on Agriculture of the Legislature of this State some time ago there is a fund of information as to the extent and importance of the honey industry of this State which is well worth repeating at this time. On those points Mr. Clayton said:

"The number of beekeepers engaged in the production of honey for market is about two thousand. They produce annually 400 carloads of 15 tons each, equal to 12,000,000 pounds of honey, and 50,000 pounds of wax. The value of these products at shipping point is over $700,000. The amount of capital invested in bees and bee fixtures (not including land), is over $1,000,000. Invested in manufacturing plants, such as planing mills, box factories, tin, zinc, galvanized iron and wax working machinery, dependent in whole or in part on the bee industry, at least $250,000 more. A full crop of honey represents a yearly expenditure by us of more than $60,000 for tin cans alone and $12,000 more for box lumber, to say nothing of the thousands paid yearly for the many other articles used, such as nails, wire screens, paint, glass, lumber, etc.

"The industry covers the whole State, but is most highly developed in the south and south central portions and adds largely to the assessment roll of almost every county. The twelve counties having the greatest honey interests, namely, Los Angeles, Riverside, San Diego, San Bernardino, Ventura, Orange, Inyo, Kern, Tulare, Kings, Santa Barbara and Fresno, have about one-fourth of the population and fully half of the beekeepers of the State. The great alfalfa region in the central portion of the State and even the far northern counties are rapidly becoming producers of honey.

"A few years ago it was something unusual to see a carload of Fresno or Tulare honey. Last year little Kings county alone produced more than a dozen carloads. The southern end of the San Joaquin valley—Kern, Tulare, Kings and Fresno—ship anywhere from 50 to 125 cars annually. Then there is Merced, San Joaquin, Sacramento, Colusa and other counties I could name. Some of the finest comb honey I ever saw came from Grand Island on the Sacramento river.

Making Bees Swarm.—If bees continue to swarm out and go back for a day or two, the probabilities are the queen is unable to fly. Swarm them artificially at once, by shaking nearly all the bees and the queen from the combs into an empty hive. There are probably several queen cells on the combs of brood which will furnish the new colony with a laying queen.

Mrs. Benham—I wonder what people wear in heaven?

Benham—I suppose you will want the most expensive things, the same as here on earth.

Mrs. Benham—That needen't worry you; you won't be there to pay for them.—Kansas City Indepeident.

SUMMER FALLOW.

The practice of summer fallowing is probably almost as old as agriculture though many feel that it is a practice of more modern discovery. Without question in many sections exceedingly rich soils in humid countries it has proved of great advantage. Also in arid countries, it is possible that the succeeding crop will be far greater than it would otherwise have been. But, under the condition which prevails in most arid sections, we believe a serious mistake will be made in the use of summer fallowing methods. Notwithstanding that, we notice the following in the Deseret Farmer:

"The practice of leaving the land fallow or uncropped every other season, or in some instances every third season, is followed on many arid farms throughout the West. It has been discovered that this method results in better yields than when the land is continuously cropped.

* * *

On our arid farms, however, the great object in fallowing is the storing up or conservation of moisture for the succeeding crop. By proper methods or tillage the precipitation of two years may be stored in the soil and can be drawn out by the crop when needed.

* * *

While the practice of summer fallowing is not to be commended on many of our small, intensely cultivated farms it certainly has its place on the arid farms.

* * *

In the same article the Farmer recommends the use of green manuring for the purpose of adding humus to the soil and bettering its mechanical condition. On this last point, we think the Farmer is eminently correct, but in the matter of summer fallowing on arid sections we think a word of warning which we heard from Professor Withycome, of Oregon State Experiment Station at Sacramento about a year ago is worthy of being repeated. The warning was in effect that in the arid sections, especially where a high degree of heat prevails during much of the year that there is great danger of burning of the humus and leaving, instead of a friable, easily worked soil, a putty-like condition which would in the course of years become so serious as to practically destro ythe soil until renewed by artificial means. "Of course," Professor Withycombe said, "this might exist for many years and on rich soils of the more humid sections it might be continuer indefinitely, but in the arid sections it must either be stopped or the condition which prevails in some parts of the San Joaquin valley where summer fallowing has been followed for years would confront the farmer." We believe that Professor Withycombe is right and that while the succeeding season shows a better crop because of this same burning out of the humus and changing it over into available plant food, yet it is paying a fearful price in the ultimate destruction of the soil. The one thing lacking in nearly all soils of the arid sections is humus and every possible means should be availed of to not only prevent loss of the humus but to add to it. In that respect, the recommendation of the Farmer is wise, but in its recommendation of summer fallowing in arid sections we do not believe that the season should be allowed to blind the immediate returns of the summer eyes of the farmer to the systematic destruction of the land.

REFINING BEESWAX.

Editor Cultivator: I have a lot of beeswax which, in running into cakes I find difficulty in separating the wax from the sediment. What is used to settle the dirt or free the wax from it?—S. J. L., Lemoore.

There are several methods of refining beeswax—by centrifugal force and wax press, solar extractor, etc. All of which require more or less expensive appliances. We give the following from Root's A B C of Bee Culture, which perhaps may give the required information to our inquirer:

"Our tank is a little over three and a half feet in diameter, and about five feet high. Water is run into it to a depth of twelve inches, and then 1500 pounds of wax is thrown in, making it about full. The mass is then heated by means of a jet of steam from a pipe projecting down into the water from the top. When all the wax is melted, the acid is poured in. If the wax is so dark as to make brood foundation, seven pints of acid is used; but if light enough to make surplus foundation, not more than three quarts is used. If the wax is already of good quality, so small an amount as two quarts of acid will answer. On the average, therefore, we use three quarts of acid to eighty gallons of water for 1500 pounds of wax. C. M. Doolittle recommends using a pint of strong vinegar in one quart of water for every ten pounds of wax. The vinegar may be used in place of sulphuric acid, but where a large lot of wax to be rendered the acid is far cheaper. Soon after this is poured in, the color of the boiling wax will be seen to grow lighter, and, after a minute or so, the boiling is stopped.

The steam pipe is now drawn out, and the tank covered with a cloth or carpet, and allowed to stand as many hours as the wax will remain liquid, or about twenty-four hours. At the expiration of this time the water and acid will have settled to the bottom by reason of their greater specific gravity; and the acid, in turn, having a greater specific gravity than that of the water, will settle to the bottom of the water; and th econsequence is, that the wax itself, after being purified, is allowed to become thoroughly cleansed of any residue of acid, and the dirt accumulation will all have settled to the bottom of the wax and into the water. The melted wax is now drawn off from the top, and poured into any sort of receptacles with flaring sides. When the wax is nearly to the bottom, or when it shows evidence of coming near the dirt, the rest is allowed to stand. As soon as it is caked in the tank, it is lifted out, and the dirt clinging to the bottom scraped out.

Without the Steam-Jet—But suppose you do not have steam, and can not very well have access to it. In that case you can use, in a smaller way, a large earthenware kettle. Into this put a small quantity of water, and, after it has come to a boil, put in a cake of wax. When melted, add the acid.

"If this is too slow and tedious a job, a large iron kettle that will hold seven or eight pails of water may be used. Fill this kettle about half full of water. Start a fire under it; and when the water boils, put in the wax. When melted, add the proportionate amount of acid. Keep hot for a few minutes, and the nallow the fire to die down. As soon as all the particles of dirt have settled in the water, dip off the free wax on top, being careful not to stir up the dirt in the water.

While the iron in the kettle may be attacked slightly, yet it will do no particular harm. When through with the kettle, clean it out with boiling water and rub over with grease."

Shade is appreciated by stock as well as by humans.

RANCH FOR SALE

13 acres 12 miles from Los Angeles, near Pacific Electric. Cement ditch and paid for, water 15 cents per hour. For particulars address owner. D. F. CONANT, R. D. 1 RIVERA, CAL.

SHORT PEACH CROP.

Peaches are very scarce in the orchards of Sacramento county this season but in the Vacaville and Yuba county orchards they are reported as promising better. At the present time it would appear that all over the State the crop is spotted at best, and will very probably fall below normal.

* * *

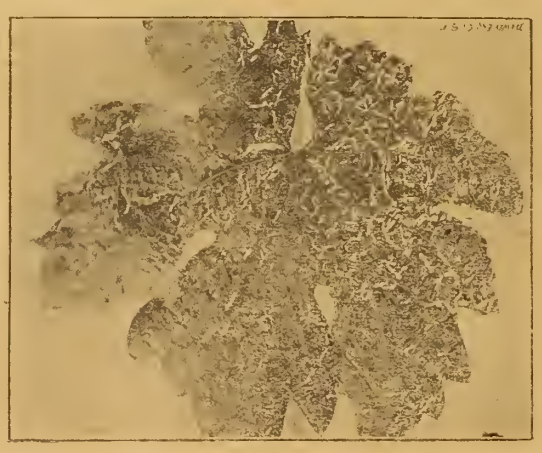
SATISFACTORY FLOWERS.

We do not know of three more satisfactory or easily grown flowering plants for out of door decoration in the northern and coast sections than roses, geraniums and fuschias. In our climate these plants grow to enormous size, without much attention and are generally loaded with blossoms. They can be had of all colors and shades of color, are perennial and do not need replanting each spring, and for a fence cover or a porch corner we do not know of any more showy and desirable flower than one of the geraniums or a strong growing fuschia.

* * *

THE GRAPE VINE FLEA BEETLE DOING DAMAGE.

Numerous complants have reached the office of the State Horticultural Commission as to damage now being done in the vineyards by that old and common pest of the vine, the grape leaf flea-beetle (Adoxus vitis.) This is by no means a new pest in the vineyards of the northern counties and every season it does great damage, especially to the table grapes by its depredations. It not only perforates the leaves but also attacks the stems and the young grapes, causing the berries to crack as they increase in size and rendering the fruit unfit for the market. In many cases the stems are entirely girdled and the supply of sap cut off, stopping the growth of the bunch. This season the pest seems to be especially bad on the Flame Tokay grapes in the vicinity of Sacramento, and the growers of table grapes there are threatened with considerable loss. It is too late in the season now to do much toward overcoming the pest, but in the early season they may be checked by the use of the Paris green spray. According to a description of the insect in a bulletin issued by the State Board of Horticulture in 1891, the beetle is nearly a quarter of an inch in length, some black and others reddish brown. The base of the antennae and the tibae are reddish. They attack the leaf, cutting long narrow slits, and where very numerous will kill young vines unless checked in their depredations. The appended illustrations will give a good idea of this pest and its work. The Modesto News states that "gardens and orchards in the vicinity of Hickman have been invaded by flocks of diabrotica, a species of lady-bug," which have done a great deal of damage. It is a serious matter for the lady-bug, which is always our friend, to be mistaken for the diabrotica, which is always and under all circumstances the worst of our beetle pests. There is no resemblance between the diabrotica and the lady-bug, either in appearance or habits, but we have known people to gather and kill the lady-bug because they knew the diabrotica was a pest and so concluded that all lady-bugs must be. We once visited a garden in which we found the owner industriously gathering all the lady-bugs he could find and dropping them in coal oil, and he had spent several days in gathering up and destroying his best friends because he found them on his plants. The diabrotica is a longish, green beetle with stripes or spots; it has a very prominent head and long feathers. We have no green lady-bugs, and all our lady-bugs are nearly hemispherical, their heads are close to the thorax, and they have no distinct neck, while their feelers are very short. People will always be safe in destroying the diabrotica, but will make a mistake in destroying the lady-bugs, and every farmer and fruit grower should learn to distinguish between them.



The Grape Vine Flea Beetle (Adoxus Vitis) and its work.

GIVING A GOOD FRIEND A BAD NAME.

PRICKLY PEAR IN AUSTRALIA.

The Department of Agriculture in Queensland offers £5000 for the discovery of some means to eradicate the Prickly Pear cactus. It stipulates, however, that the cost per acre shall not exceed a reasonable sum. One would think that the seeds of the Prickly Pear enveloped in dense pulp would lie where they fell, unless transported by birds, whose flight would not be very long, but this terrible cactus is traveling over the world with unaccountable speed. It is a nuisance in India, a pest in South Africa, there are complaints in the Soudan, and we hear of it in Uganda. The thing is not altogether without virtue. Thrown upon the fire for a moment to burn off the spines, it may be mashed into a food for horses or cattle, very valuable in times of drought. But this service is not required every day, whilst the mischief it does is incalculable. In thinly peopled districts it has entirely stopped the roads, compelling travellers to circle around the growing mass.

PREPARING FRUIT FOR EXHIBITION.

The Kansas Experiment Station has issued another of its valuable little bulletins, this time touching upon preparing fruits for exhibition. Its general suggestions are so good that we give nearly in full:

Every fruit and vegetable that is to go on exhibition tables should have the best possible opportunity for development. This will usually require thinning, and sometimes a little pruning in order to give the fruits a chance to color. Every exhibitor must consider his exhibit from the judge's standpoint. While there are at present no authoritative standards, most expert judges have an outline they follow more or less closely. A general plan for all fruits, established by the Massachusetts State Board of Agriculture, is used in its present or a slightly modified form by many judges. It is as follows: Quality, 20 points; form, 15 points; color, 15 points, size, 10 points; uniformity in size, 20 points; freedom from imperfections, 20 points; total for perfection, 100 points.

Nearly all points are considered from a commercial standpoint. The over-sized fruit is not wanted by the markets, and over-grown specimens are likely to be cut by the expert judge. Quality is a hard point to handle, especially with fruit not yet ripe, and in such cases is often disregarded or estimated by the form and general appearance of specimens. In competions of storage fruits, however, it is of special importance. Uniformity of specimens is a most important matter. Fair-sized fruits of even form and color of the proper type make good plates. They show to much better advantage than uneven specimens. Freedom from blemishes should be insisted upon. A fruit injured by insect, disease or accident is not marketable and deserves a hard cut. Some older judges disqualify such fruit from competition.

Fairs should be educational in character. Those who attend should see only good specimens, such as the world markets want, if they are to be benefitted by their attendance. The grower should know what is wanted, and if he does not, the fair may be a valuable school for him.

RURAL DELIVERY.

There are, at this time, 4708 applications for new rural delivery routes before the postoffice officials. The new routes are being established at the rate of about 600 per month. Thus far, the service has reached about one third of the rural population of the country and is costing in excess of $20,000,000 a year. This is causing a roar on the part of some of the commercial people of the country, claiming this service should be dispensed with to reduce the deficit in the department. To this, the farmers naturally reply "Cut out the graft with the railroads where several times the rate which the same corporations receive from the express companies is paid by the government, when the deficiency will be wiped out and the department self-supporting." The howl which is going up for the discontinuance of this magnificent rural service will never win out. The tendency of the United States has not been backward in any marked degree.

The importance of the Bermuda onion industry to the farmers in the neighborhood of Coachella and Mecca has been spoken of in the Cultivator heretofore and we now note that the Submarine is speaking of the great possibilities of that section in the production of early onions. Some great profits have been secured during the past season. These, in some instances, have been reported to be as high as from $400 to $700 per acre. It is said the field in which this industry flourishes is very limited, only favored sections of the south which are free from frost giving the right condition. This gives comparative freedom from competition and it is claimed will cause a continuance of the favorable prices which have prevailed in the past.

The date crop at Mecca from the government experimental plot has been harvested from trees which were planted last year. These trees are in charge of B. G. Johnson, who has given them care for the past year. These trees were secured from Algeria and the harvesting of these few trees so soon, though it consisted of only thirty dates, gives addedhope of a successful outcome of this experiment.

CITRUS FRUITS

By C. A. Day, Pasadena

PHYSICAL CONDITION OF ORCHARD SOIL.

Cultivation, irrigation, fertilization and physical condition of the soil, rank as the most important factors in successful citrus fruit culture. I believe that we citrus fruit growers are inclined to give less attention to the improvement of the physical condition of the soil of our orchards than almost any other feature of orchard culture.

Soil in good physical condition is that state which is favorable for the action of nature's forces in promotion of plant growth. I can best illustrate what I mean by a soil in proper physical condition by referring to virgin soil that has never been cropped or cultivated by man. The soil of the forest or woodland ranks in physical condition as the nearest to perfection. This soil contains a large amount of organic matter, as decaying wood, leaves and roots. Such a soil is rendered porous by the large amount of humus and vegetable matter which it contains. The soil being porous readily admits the water and air, and the decaying vegetable matter absorbs and holds the water and in the process of fermentation increases the soil temperature. Such a soil, when cleared of forest growth, responds quickly to the demands made upon it in the growing of farm crops. This soil contains a good store of nitrogen in a form to be readily converted into available plant food, but what is of fully as much importance, the soil conditions are such as are favorable for the action of nature's forces or agents in producing the necessary chemical changes of the soil elements that fit them for the use of plant and tree. The favorable conditions of this virgin soil is that it is mellow and friable, with its many well aerated pores that allow the roots of plant and tree to grow unhindered in any and every direction, and to place their absorbing surfaces in vital touch with the soil grains and soil moisture.

* * *

Effect of Cultivation on the Physical Condition.—Cultivation of farm crops, as usually practiced tends to lower the physical condition of the soil. On this point one author says, "Our method of tillage tends inevitably to so alter the texture of surface soil, especially if they are heavy, as to make the spread of young roots through them more difficult and hence thorough stirring for tilth becomes more important than it was in the virgin state. The frequent stirring tends to break down the compound grain structure, so that the action of rains, and of stirring when too wet, causes the soil grains to run together into masses of so close a texture that the young roots find difficulty in making their way among them, and are insufficiently supplied with air, even if they succeed in doing so. Those of us who have been farmers have noticed the improved condition of grass land when broken up and put to another crop. The conditions of soil continually cultivated are the very adverse conditions which we as orchardists have to contend with. As citrus fruit growers we are handicapped in not being able to use the method of rotation of crops. We are forced by constant cultivation alone to maintain our orchard soils in good tilth or physical condition. By cultivation alone we try to pulverise our cemented soils and admit air and water; by these methods we fail to secure the best possible results. We are all convinced that we need more humus and vegetable fiber in our soils. With an increase in the amount of humus and vegetable fiber in our orchard soils we not only increase the supply of available nitrogen, but aerate the soil and increase its water holding capacity, which will result in an improved condition of our citrus trees. We cannot seed down our orchards to grass or resort to a rotation of crops, but we can, by growing green-soiling crops of peas and lupines and plowing them in, add to the present supply of vegetable matter in orchard soils and the decaying roots of the legumes will contribute to the same result.

Stable manure is valuable for the same purpose and it is believed that stable manure is of greater value in improving the physical condition of the soil than for the fertilizing material in it. An excess of stable manure does not improve the quality of the orange and must be used with caution. In many years in general agriculture, clover has been used in a crop rotation system, not only to secure improved physical condition of the soil, but to add to the store of available nitrogen.

All leguminous plants, such as the clovers, beans, peas and lupines add large supplies of nitrogen to the soil in which they grow. One of our most noted agricultural scientists says: "Barnyard manure has marked effect upon the amount and disposition of soil moisture. When coarse manure is plowed under, its first effect is to act as a mulch to unstirred soil by breaking the capillary connection between it and the surface layer."

It is a fact long ago observed that increasing the organic matter in the soil increases its water holding capacity. This being true, it is to be expected that the surface foot would be more moist as a consequence of manuring. But by experimental work and observation it has been found that there was an increased amount of moisture in the three surface feet and that the influence of the manure is felt below the level to which the manure is applied.

Green soiling crops will produce an effect on soil similar to that of manure. A part of the observed difference in the water content of manured and unmanured soils is to be explained by the fact that the rate of surface evaporation is diminished by the application of stable manure. Sawdust and fine shavings from the mills have been used with good results in the improving of the physical condition of soil. Of course this material used has no fertilizing element, but is beneficial in loosening the soil and rendering it capable of absorbing air and water.

An exchange gives a remedy for ants injuring fruit trees, stating that in many sections the pest of ants is very great and is doing much injury. This is probably an entire mistake for injury of trees by the ant is a new feature if it ever occurs at all. The ants are doubtless on the trees seeking the honey dew deposited by the plant lice or aphis. The aphis do much injury, especially to the young tender growth and should be removed by a weak kerosene emulsion or even a spray of water from the hose is sufficient to destroy them. Once they are removed, the ants will disappear.

Some considerable interest has been manifested in California papers by accounts of the working of a new orange wrapping machine which has been tested in Riverside. It is claimed that wraps are much more rapidly placed on the fruit than can possibly be done by hand; also that work is uniformly and perfectly done. If this can be done without adding to the already serious line of injuries which are often given to fruits in packing, it may prove a great labor saver, but the idea advanced by many, that labor-saving machinery has been the cause of rapid increase in the percentage of decay, may have some foundation, in fact. However, that is a question which the managers of packing houses will probably look into and if found a success will add to the economy so necessary in placing our oranges in marketable condition. This does not dispense with the packer by any means, but, instead of wrapping the packer will simply place the fruit in boxes ready wrapped.

SHORT EUROPEAN ORANGE CROP.

Reports from Europe indicate that the crop of oranges the coming year will be exceedingly short. Some estimates make the claim that the output will not be more than twenty-five per cent of the average.

In the Sacramento Union we note that the orange growers of the south of Europe have been further troubled by the appearance of an insect known as chrysomphalus minor, which, they say, is an importation from America. The destructive tendencies of this insect have been intensified by European air and very many of the trees are dying. The chrysomphalus is said to attack not only orange trees, but also lemons, magnolias, camelias, palms and laurels.

Imperial valley has made a number of experiments in tomato planting this year and the Press refers to the work of a farmer near Holtville who did exceedingly well with some early tomatoes at very high prices.

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

CARE OF FERNS.

Of the thousands of ferns found throughout the world, only about a score are very generally grown. Some grow in water, some in the driest of soils, and some thrive only in the saturated atmosphere of the tropics. Several of the most desirable will not endure a slight draught of air and can only be successfully grown in Wardian cases, and a hundred reasons might be given why we cannot grow all ferns with the care ordinarily given pot plants.

Soil is not of the first importance, though if proper soil is present, better results will be obtained, and the or no sunshine, but need plenty of light.

For garden planting the common sword fern is very satisfactory as it does not droop and get its fronds dirty, but for pot or hanging basket the variety known as the Boston fern is the more popular, and for small pots nothing is more desirable than the neat little cordata compacta. Among the ferns having a typical fern leaf none will give better satisfaction in house or garden than Pteris tremula, though it is too rank in growth for small pots. Several maidenhairs are used as pot plants but are not so satisfactory as the others mentioned. A. cuneatum is the best, will stand con-

The Boston Fern

The Best Maidenhair. Adiantum cuneatum.

care of the plants much simplified. One-half garden loam, one-quarter sand, and the balance of leaf mold will make an ideal soil for the ordinary ferns. Watering must be most thoroughly done about twice each week. The safest and best system is to stand the pots in a vessel of water until the water has thoroughly soaked all the soil. This stage can be told by the soil showing dampness on top. If the soil and drainage are good this will consume but a few minutes time. When ferns are in good, healthy growth they should have an occasional feed of fertilizer They require little siderable abuse and neglect.

Many people include among the ferns the several species of asparagus, and one of them, known as the asparagus fern, requires a similar treatment. Asparagus Sprengeri, the most enduring of all, is a gross feeder and is perennially thirsty. It must also be shifted into a larger pot once each year or have a change of soil every six months; this to be supplemented with liberal fertilizing.

DRAPERY OF THE VINE.

Vines have a most important mission to perform in the decoration of the house, and no dwelling, even of the most beautiful architecture, is complete without their graceful drapery. They give an artistic touch that nothing else can supply, whether it be a cabin or a mansion. Train a rapidly growing vine over bare walls and it transforms the most unpretentious of dwellings into a thing of beauty, and when trained around sunny porches the vines not only beautify, but add much of comfort to the home in summer.

Vines are of little trouble after they are planted, will live forever, and though some of the prettiest climbers will be found in the foliage class, many of them have flowers that are conspicuously beautiful.

LIVE OAKS FOR STREETS.

It is much to be regretted that a few people have so hastily passed judgment on the live oak without giving it a fair trial. A single year's growth is not a fair test with any tree or plant. It is a curious fact that the live oak usually requires a year in which to get started, and oftentimes does not make a single inch of top growth—The next year it may grow ten feet. We have heard of this tree making ten feet of growth in a single year—we know of one at South Pasadena, in the grounds of Mr. H. A. Perkins, that has grown six feet from an acorn in twelve months.

The growth of the live oaks along Pasadena avenue, Highland Park, during the past year (its first year) has been good—all that was expected of it. A pioneer in tree planting, and one of our most prominent men, Mr. F. Q. Story, of Alhambra, says that he has observed that under favorable conditions the live oak makes just as satisfactory growth as the average tree used for street planting.

FUCHSIAS.

Few of the more common garden plants conno to all countries arrive at greater perfection in California than the fuchsias. This statement perhaps needs tempering with "where proper soil, care, etc., is given them." In Northern and North Central California they thrive more universally than in the southern part of the State, where the lack of humidity relegates them to the north or east side of the house.

Fuchsias are very variable in size and habit; one in New Zealand forms a tree 30 to 40 feet high, while F. procumbens from the same country and common in this State, is a trailing plant but a few inches high. The fuchsias we usually grow might be termed herbaceous shrubs. Some species have been grown for hundreds of years and the flowers and foliage vary greatly in appearance. Added to this the horticulturist has, by crossing, produced an endless variety of forms.

After we have settled down to a healthy garden taste, when we are through pampering weakly exotics that we cannot grow, fuchsias will be more commonly grown and appreciated on the Pacific coast. They are among the easiest of plants as regards culture, and their ultimate size is largely in the hands of the grower; they may be shrubs of a few feet, or they may "go on a rampage" to the roof of a building. Any garden soil seems suitable and the most ordinary experimenter may propagate them either from seed or cuttings. When buying plants from the nursery, aim to get the young, soft-wooded ones rather than those a year or more old. When thoroughly established in the garden, they may occasionally be fertilized, but if the soil is already fairly rich in plant food, they are not very responsive. When one considers how little care they require, compared with the results usually obtained, it is a wonder they are not found in every garden.

LIQUID MANURE.

The best all round liquid fertilizer can be made from cow manure. Make the liquid in a barrel or tank, and when drawing it off dilute to about the color of weak coffee and apply once every five or six days, according to the needs of the plants. This will do both for roses and carnations. If the cow manure is not obtainable, sheep manure will suffice, or ordinary stable manure. If sheep manure is used, care must be taken against using it too strong or more harm than good will result. In feeding with liquid, it is well to know that a weak solution applied often is better than stronger ones given at longer intervals.

When it is desired to give lime in any form, either sprinkle the lime over the surface of the bed, to be washed into the soil with the watering or make a barrel of lime water, and use it on the beds, clear. There is no danger of getting the lime water too strong, as the water will only absorb a certain per centage of the lime. Soot is good to be used when growing decorative plants, as it helps in furnishing good color to the foliage; but for roses and carnations it is not a necessity.

Roots need moisture these hot days.

General Agricultural Notes

THE WANDERINGS OF ALFALFA.

Talk about blue blood; that would be a proud member of the Four Hundred who could trace his lineage back as far as can a certain cousin to the clovers that may occasionally be picked on our lawns and vacant lots and by the roadside. This scion of an ancient race is alfalfa, which is cloverlike in foliage and flower, but the blossoms are blue. Twenty-five centuries and more ago, when Athens was the hub of the universe and all the outer world was considered barbarian by the Greeks, alfalfa dwelt unostentatiously in the valleys of that part of Western Asia inhabited by the Medes and Persians. When the wars arose between those people and the Grecians, and Darius made his famous expeditions into Greece, our little plant appears to have gone along. Perhaps its seeds were transported by accident in the camp baggage of the Persian hordes, or possibly some enterprising Greek prisoner escaping from Media, brought seeds home with him and established the culture of the plant in his native country. At any rate, into Greece it came about five centuries before Christ, and doubtless helped to make Alexander's charger Bucephalus the horse he was. When Greece became absorbed into the Roman Empire, alfalfa won the favor of the conquerors. who cultivated it extensively for fodder, for their army horses, and introduced its culture into Italy. The poet Virgil mentions the plant in the Georgics under the name of Medica—a word which in spite of its looks has nothing etymologically to do with medicine, but simply means the herb from Media.

From Italy its culture spread northward into Middle Europe, and westward into Spain. It was in the latter country that the name alfalfa, an Arabic term, became attached to it, indicating that it was under cultivation in the Spanish peninsula at the time of the Moorish occupation.

When Spain extended her sovereignty across the Aatlantic a new world was opened for alfalfa to conquer, and it made good use of the opportunity, establishing itself as a blessing in the bloody trail of devastation which the Spanish inquistadors of the sixteenth century left behind them in Mexico and Peru. In arid regions, where no succulent grass would grow, and where clover would wither away, the alfalfa was sown, and by reason of its great length of root, which enables it to draw moisture from a great depth, flourished and increased. Down the South American coast it made its way as far as Chile, and from that country it was brought to California a few years after the admission of the Golden State to the Union. Thence its fame as a valuable hay plant possible of growth in the dry lands traveled throughout the West, until now it is the staple fodder crop on the Pacific Coast and in the Rocky Mountain region, from Montana to the Gulf of Mexico. It will soon be a staple all over the East as it has become already in many sections.

Easy Foote—De more a man does de more he's capable uv doin', Dusty Drowse (shuddering)—Yes; one crime leads to anudder.—Judge.

Far beyond the smiling skies,
Little toils thous didst not shun,
These are treasures that shall rise.

OPPOSITION TO PARCELS POST.

Antiquated business methods die hard. The local merchant who charges excessive prices for his wares, believes the trade of the farmers and other people of his vicinity belongs to him and bitterly resents their going elsewhere to make purchases, even at much lower prices, is stoutly resisting the tendency of the times. Merchants of this type must sooner or later yield to the inevitable; but they are still numerous, and the desperation with which they fight for the old-time privilege of exploiting their customers puts them more "in evidence" than ever. Merchants of this class are perpetually grumbling about the "catalogue houses," as they call the firms which do a mail order business in merchandise. They are organizing under various guises to fight the mail order business and, because they think it will increase that traffic, to oppose the parcels post. They are enlisting in this war many of the newspapers which depend upon them for advertising patronage. The war is even extended to their recreant customers who are not only visited with their displeasure because they have been "disloyal" enough to buy goods from mail order houses, but threatened with more severe treatment.

The truth is that the war against the mail order houses and the parcels post is against the interests of the farmers; and if the farmers make their influence felt in public affairs, notwithstanding the selfish interests of the express companies, which charge excessive prices for service much less satisfactory than that of the postoffice department. The mail order business is here to stay and will grow to vaster and vaster proportions, with or without the parcels post. The local merchant will always be with us, but will be required to meet existing conditions, accept smaller profits and do a larger volume of business. If he is wise, he will go into the mail order business himself wherever practicable and give up a needless struggle against changed conditions. The parcels post is right and the people should insist upon its adoption without needless delay.—Homestead.

CARE OF TOMATO VINES.

My experience has taught me that in order to grow a good, large tomato, proper care must be given the vine. Of course it is necessary to set the plants in fertile soil, but this is not all. The vine must be kept pruned and off the ground.

I find the best plan for keeping the vines from falling over is to drive a strong stake down beside each plant when it is about 1 foot high, and tie the vine to it with a heavy string. As the plant grows, tie another string a few inches above the first and so on. Always keep the little suckers, that come out at the juncture of the leaves and stalk, pinched away. They will rob the vine of the life that should go into the tomatoes. It is often beneficial to cut the lower leaves away, for they decay and hold unnecessary moisture.

Decaying vegetation and dampness cause the young tomatoes to rot. It is a good plan to mulch the vines with straw or grass. One year I pursued the staking and pruning plan with 25 or 30 vines. The tomatoes grew extra large, were well-formed and firm, and ripened early and evenly. I raised enough for my family to use during the summer, had plenty for canning purposes, and sold several bushels.—O. J. Farmer.

LOW PRICE FOR POTATOES.

Texas potato growers are in a hard way because of exceedingly low prices of potatoes. With mistaken ideas as to the price for this year's crop, plantings were exceedingly large and the freight rate rather high, which has put the poorer potato grower almost out of business. The railroads have now conceded an emergency rate but the added handicap of low northern markets still has serious effect upon the local condition. At Denison it is claimed that no price what ever could be offered for the spuds which would justify shipping under present conditions.

The potato is a native of the elevated regions of Chile, Peru and Mexico, but it is now one of the most widely cultivated and valuable esculent tubers. The ideal soil for the potato is one that is well pulverized, light, rich, cool and moist. Where the soil tends to pack and run together after an irrigation, as is frequently the case in flooding, it is of more importance to have the potatoes in a light and loose loam. Again, the potato thrives in a relatively cool climate, or during cool weather in the warmer sections. As a matter of fact, the best potato growing sections, as a rule, are in the elevated valleys where it is naturally cooler, or in the mountainous districts.—Fabian Garcia.

Some study shows the need for more.

Sievert Oil Burners

Superior to all others. A perfect system of heating with distillate oils. Non-explosive, safe, simple and economical. Made in sizes for Stoves, Ranges, Water Heaters, Furnaces and Boilers. Send for Circulars.

Thomas Lawson's Remedy.—The author of the famous articles on "Frenzied Finance," which have stirred this country and Europe, in the past few months, as they have not been stirred in any previous time, lectured this week at Kansas City before a Chautauqua assembly. After recapitulating the ideas and charges heretofore advanced, Mr. Lawson made bold to assert that the only remedy left to the people, to curb the greed of the money power, is to sell back to it the stocks and bonds bought of it, and hereafter keep out of the market of the Standard Oil propositions. By so doing, he thinks, the money magnates will be driven out of business, and the money which they have stolen will find its way back into the pockets of the people. We do not agree with him in his declaration that "there is nothing in municipal ownership of public utilities." Experience along this line demonstrates that there is much in public owuership, aud the fact that private corporations can afford to offer such enormous sums over the cost of creating these utilities, is proof that there is great profit in stocks of these propositions. We do not find the cities owning public utilities anxious to dispose of them. They have proven profitable, as well as affording cheaper rates in gas aud water to the people. So long as they do this they are valuable and desirable both from a public and individual point.

Of course, Mr. Lawson is an extremist, but his articles and his lectures will serve to draw the attention of the country to the danger which threatens it from the overwhelming ambition of a few men to control the finances of the nation and of Europe. He takes no stock in laws Congress may enact, for he thinks its members remain under the thumb of half a dozen money magnates who will not permit statutes to be passed which will tend to curb their possibilities to still farther amass wealth.

Here again Mr. Lawson is wrong—as we believe. The country has made up its mind that the trusts and combinations must let go their grip on the people, and if the members composing the two branches of Congress are too weak to stand by the President in his demand for a fairer deal in business matters, they will be left at home and men will be selected as the people's representatives who have the manhood to vote for those laws which insure a "square deal" to every man in business.

The issue is drawn and the people will not be trifled with any longer.

* * *

Our State's Independence.—The people who reside in California, and have watched its growth in population, and its development in resources, are proud to note that the financial condition of the State is now a cause for congratulation.

Within the past month school bonds and sewer bonds to the amount of about two million dollars have sold at a premium and have been purchased by banks in this State.

These investments are the best possible proof of the faith Californians have in their State. They show, too, that our monied men see the advantage of keeping money at home, and paying interest at home. Heretofore money has gone out of the State by millions upon millions. Now we have reaches a point where we can save this interest instead of sending it east. We have paid to eastern bondholders in the past many millions of dollars. Had the State not been enormously rich in itself, this drain would have bankrupted it. We have paid interest on railroad bonds, municipal, county, school, irrigation bonds, and goodness knows what other bonds we haven't paid interest on, and yet, in the face of this constant drain the State has continued to develop and prosper, until today we are in a position to purchase our own bonds and bidders will pay a premium for them.

This general investment of California capital in California securities marks the opening of a new era in the State's development. Like all new countries it has been more or less dependent financially on older communities, where wealth has accumulated. Now it is fast showing its ability to stand alone. With the greatest financial institutions of the country actively bidding, California bankers are finding it worth while to make the best offers for California securities.

There are few States of the age of ours which have reached this stage of financial independence. Certainly none have shown greater faith in the future of the Commonwealth. It is indeed a proud position to reach, when we can say to the eastern purchaser of bonds, "you must outbid our own bankers or we will sell at home." All hail our grand young commonwealth!

* * *

Value of Pumping Plants.—If cotton is king in the South, water is king in California. Ever since citrus growers and farmers in general began the work of cultivating the soil they have learned that the desert, in California, may be made as productive as the richest loam of Kansas or Iowa by the proper application of water. Time was when the orchardists depended upon the surface streams and springs to supply his demand, but it soon became apparent that these sources of supply would be indaequate, and resort must be made to pumping plants to command the water needed for the life and prosperity of the orchard.

By the improvement and final perfection of pumping machinery and the assurance of cheap fuel through the discovery of oil in the State, a wonderful stimulus has been given to agricultural undertakings, and lands which before the introduction of pumping plants were practically useless, have become of immense value and readily find purchasers.

Under the decision of the Supreme Court of this State, in the well known case of Kato vs. Wilkinshaw, and in other cases as well, it has been decided that water can be appropriated from running streams, or percolating streams, in sufficient quantities for the necessity of the land owner, who has only to apply the necessary machinery to draw from the ground the water he may need.

This doctrine is well settled and should be remembered by investors who can, by the use of pumping plants make their lands as fertile as those adjoining the Mississippi river. When it is taken into consideration that by expending a few hundred dollars in sinking a well, and installing a plant, the value of the land so irrigated, is enhanced to four times its original value, the wisdom of the undertaking from a financial point of view is apparent. Indeed the time has come when every ten acres of land under cultivation should have an irrigating plant of its own, so that it may be independent of the complications or whims of irrigating companies. No owner of land need fear that the water beneath him will be denied his use, so long as he confines it to reasonable application of the soil, but he should remember the finding of the Supreme Court, to the effect that he can take from his land only so much water as shall be necessary for his own use without injuring prior appropriators and overlying land owners. He can not supply irrigating companies with water drawn from his own land if thereby he works an injury to overlying property. This is the only doctrine to keep in mind, and at the same time, applying always the rule of trespass.

The new settlers in the State will be interested in knowing these well defined doctrines, for they are usuallly an enterprising class of men who are anxious to improve their purchases and who realize, in a brief period of residence the living necessity of securing water of their own to secure the best agricultural results, as well as the rapid enhancement of their lands.

* * *

Clean Fairs.—The season for district and State fairs is now at hand. The Cultivator wants to utter a suggestion early in regard to making them clean of objectionable exhibitions. There has been an improvement iu this direction during the past few years, but there is room for still greater improvement.

The managers of the district fairs, as well as the State fair, have been at work for some time, planning for this season's exhibition. Their policies are outlined, doubtless, and it may be nothing we can suggest will influence them in changing their plans. However, the Cultivator will say, that to eliminate objectionable side shows, fakes and gambling devices, will add greatly to the character of the fairs, as well as to the credit of the managers.

A contemporary makes this point, in connection with clean fairs: "If the farmers will take it upon themselves to stamp out fake schemes instituted for no other purpose than to get their money, they can easily do so. They can do this in a single season, if they choose to. The farmers are the backbone of the fairs, and if they absolutely refuse to patronize questionable side shows for one season, it is not likely that such institutions will put in an appearance the following year, as they are not in the business for pleasure, but for profit."

Farmers can not exert the same influence in State fairs that they can in district fairs, but they can refuse to patronize the objectionable shows in the State fairs and thus set the seal of condemnation upon them.

Secertary Wilson, in speaking upon the financial success of fairs, said truly: "There are two sides to everything. At least that is a statement often made. There are two sides to the fair question—a financial side and an educational side. The financial side has always been put first and that is right. Unless a fair can be made a financial success it cannot exist. This is the very question that confronts fair managers. They must offer premiums for the best farm products, vegetable and animal, or nobody will go to the expense of putting products on exhibition. They must maintain grounds, buildings and other property for show purposes, and everything costs money. That money must come from those for whom the fair is held—the general public and more particularly the farming public. If the farmers are not willing to "lay down the shovel and the hoe" for a day or two and visit the fair, the managers must get revenue from some other source, hence the introduction of the side shows. Good, clean, educational sideshows are not objected to when their introduction is absolutely necessary. Gambling devices of all kinds should be prohibited. Let the farmers demand it, let the exhibitors enter their exhibits only on the condition that a clean show is guaranteed and let every farmer turn out and patronize his State and county fair. If the farmers would all attend as they should, there would be no trouble about making any State or county fair a financial success." The Cultivator's advice to the farmer's of this State is to turn out to the district and State fairs this year, and show the interest due the managers, as well as learn something from the things exhibited.

HOT WEATHER INJURES PLUMS.

Some of the river districts in the San Joaquin and Sacramento valleys report "cooked" plums in many of the orchards. Some of this is so serious as to unfit the fruit for shipping, but the weather having moderated at this time, it is hoped that damage will be less than at one time feared.

If you suspect a man, don't employ him; if you employ him, don't suspect him.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The Gridley cannery will open up this week for a month's run.

A small crop but an excellent product is the report of the raisin crop around Fresno.

The first crate of Fontainebleau grapes for the season was shipped from Vacaville on July 4th.

The directors of the Zante Citrus Association of Tulare county, have let the contract for enlarging their packing house.

Fair prices are being received from consignments of fruit now being forwarded from Sacramento and other northern points.

From the seventeen acres planted only last year the first date crop was recently gathered. While it comprised only thirty dates it marks an epoch for Mecca.

The addition to the Porterville Citrus Association's packing house is about completed, only the shingling and some minor details remaining to be completed.

Shasta county reports are to the effect that the grape crop has been practically ruined by grasshoppers which eat all the leaves from the vines and leave the grapes to be spoiled by the scorching sun.

The Colton Fruit Exchange is winding up a prosperous year, the total amount paid during the season up to date to the members being over $150,000, a sum considerably larger than that of former years.

The hot weather of last week has ripened up the deciduous fruits of the northern portion of the State quite rapidly and in some sections grape and berry crops were materially injured by the long and excessive heat.

Toluca and San Fernando peach growers are freely contracting their fruit with canners at the rate of $31 for 2¼ size clings, and $18 for the undersizes. Freestones are commanding $20 for 2¼ size and $13 for those under that size.

The Earl Fruit company last week shipped two train loads of eight cars each of green fruits from Sacramento to the London market. On arriving at New York the fruit will be transferred by lighter to ocean vessels and will be laid down in London within six days.

Under date of July 7, Geo. B. Katzenstein, manager for the Earl Fruit company, gave the Sacramento Union a splendid showing for the green fruit situation of the northern portion of the State. To June 30th there had been shipped 1181 cars of cherries, apricots, peaches, plums, pears and apples, as against 518 cars for 1904 and 788 cars for 1903.

The California Citrus Union reports to us that it received, in Redlands, 20,012,070 pounds of Navel oranges, for which it paid to the growers $235,373.29. This is very close to $1.18 per 100 pounds, or counting 70 pounds to the box, is 82 1-3 cents a box. This counts everything that was packed and the culls besides. That is to say, that every one hundred pounds of oranges delivered at the packing house, including worthless culls which were thrown away, brought to the grower very close to $1.18. That is not a bad showing, by any means.—Redlands Citrograph.

LIVE STOCK.

A creamery is being planned at Coachella, to be erected this fall.

The Santa Rita creamery located near Pleasanton, was totally destroyed by fire July 5th.

Stock raisers in the Imperial valley are clamoring for the appointment of a live stock inspector.

The Colbrook creamery at Loleta, Humboldt county, is said to be doing a fine business this season.

A new refrigerating system has been installed in the Model Creamery company's plant at San Jose.

A small creamery plant has been established by Reise & Co., on their ranch in Contra Costa county.

A company with a capital stock of $25,000 has been formed at Berkeley by Messrs. Coulter, Reed and others under the name of the Varsity Creamery Co.

The Raab Creamery company of South Pasadena, which has leased the Kings County creamery at Hanford, is turning out about 2000 pounds of butter daily at the last named place.

The creamery at Traver, Tulare county, is manufacturing about 700 pounds of butter daily, which is shipped to Los Angeles and Pasadena, as better prices are received there than elsewhere.

The Board of Directors of the Pacific Coast Trotting Horse Breeders' Association, at a meeting held in San Francisco recently, decided to hold the next race meeting at Santa Rosa, commencing August 18th.

A farmer, J. D. Vannoy, who is engaged in farming near Traver, states he is now milking thirty-five cows, the product averaging one hundred gallons daily. His returns are $150 per month and expenses but $50.

After a campaign of several months duration applying the tuberculosis test to all cows whose milk is sold in Palo Alto the board of health now announces it has completely banished tuberculosis from all herds that contribute milk to the inhabitants of that city.

Rincon now has not only a new cheese factory, but a skimming station as well, and the dairying industry ought to flourish there. A Los Angeles man has bought the old Richenberger cheese factory and opened it up as a skimming station, shipping the cream to Los Angeles. The Alter cheese factory is now in full operation, and the milk supply is about evenly divided between the two plants, with considerable rivalry for the big end of it.—Chino Champion.

After holding out for three days for a better price than was offered by the buyers the wool growers gave in and sold their crop for 27 cents, says the Ukiah Democrat. The buyers combination proved the most effective. In the warehouse there were 315,000 pounds of wool, the largest amount ever brought to Ukiah on wool sale day. At 27 cents this brought $85,050; while at 30 cents it would have brought $94,500, or $9450 more into the pockets of the growers. This sum was lost to the ninety wool sellers who have yet to learn the value of combination. The amount was an average of $100 per grower, yet one of the principal reasons anyone of the growers advance for selling at the figure he did is that he did not want to remain in town under expenses any longer.

AGRICULTURE.

The Imperial Press claims that there are more than 300,000 acres of land in the Imperial valley adapted to the production of sugar beets.

An almost total failure of the tomato crop around Fresno has been caused by the inroads of the tomato wilt, a disease seemingly beyond control.

The San Jacinto Register notes the cutting of three tons of alfalfa to the acre by one of its subscribers living on the mesa west of town. It was cut from alfalfa planted last season.

Melons are not the only product of Brawley if the item about Wm. Farr shipping in three car loads of hogs from his ranch and the further intention expressed as to bringing in 1400 head of cattle to fatten this fall is correct.

Dave Hickman has 30 acres of his 40-acre tract, two miles southwest of Orosi, seeded to alfalfa, says the Orosi Offer. He has lately harvested the second crop, the yield being 55 tons, which he sold in the shock at $4.50 per ton. This alfalfa was seeded one year last March.

The work of locating Luther Burbank's thornless cactus, and establishing the plant in the State as a forage for stock, will be undertaken by the United States Agricultural Department. David Griffith, assistant agrostologist from the range investigation division of plant industry, will confer with the authorities of the University of California about the work. He has instructions to begin the work of locating the smooth cactus plant, and will begin experiments immediately. Several places suitable for the project are already under consideration. The most notable of these are Yuma, Mecca, Santa Monica and Chico.

MISCELLANEOUS.

Work on the Oroville and Chico electric railroad will begin within the next thirty days.

A fierce forest fire destroyed several thousand acres of feed near the mouth of the Kern river canyon one day last week.

From many parts of the State come the report that the cold, backward spring will very materially lessen the output of honey.

A quarter page advertisement in a local paper calling for help to work in the cannery indicate a busy season for the Visalia cannery.

George Blackburn, superintendent of the Hopkins ranch near Healdsburg, says 1500 cords of tan bark will be shipped from the ranch this season.

The extension of the narrow gauge railroad on the Buena Vista side of the Salinas river will be ready for the shipment of produce on the 24th of July, so it is announced.

A correspondent of the Porterville Enterprise calls attention to the necessity of saving the grand old valley oaks that dot the landscape. Save them all where possible; they can never be replaced and are worth a hundred times their wood value to the country.

According to the Willits News, a woolen mill will soon be established at that place. J. S. Parker, of the Parker-Thwaite company, of Ohio, is the gentleman who is planning the mill. Beyond the matter of location the plans are not as yet made public.

The Board of Supervisors of Sacramento county granted a franchise last week for an electric line down the Riverside road leading out of Sacramento. It is the intention to extend the road into the great fruit-growing district south of Sacramento, running both passenger and freight trains.

The Hanford Journal says H. W. Roller, of Crowley, Louisiana, is investigating the feasibility of rice culture down in the lake country. A half car load of rice was shipped in, of which a large portion was planted and everything looks favorable for the enterprise.

Under the recently completed irrigation canal the Gridley colony, located two and one-half miles southeast of Gridley, is being rapidly improved. The company has sold to twenty-eight families from three to forty acres each and six dwellings are already erected while a number of others are under construction.

The wool growers about Ukiah are many of them holding for full thirty cents per pound for their wool, while others have sold as low as twenty-seven cents. Even at that price, the wool people will probably net a very nice income from this year's product, but, if thirty cents is the going price for the bulk of the crop, the ordinary producer should stick for his full price and aid his neighbors in securing it also.

The call is issued for the sixteenth annual session of the Trans-Mississippi Commercial Congress, to be held at Portland, Oregon, August 16th to 19th. At the coming session there will be the usual topics affecting rivers and harbors, internal improvements, trade relations with the Orient, irrigation and reclamation of arid lands, good roads, forestry, mines and mining and other subjects of vast interest to the Western States.

The deal which has been pending for some time by which the Associated Oil and Standard Oil companies were to purchase the oil wells and pipe lines of the Coalinga Oil and Transportation company, has been closed. The Coalinga Oil and Transportation company was a disturbing factor in the plans of the combine to regulate prices. That is why it was bought out. The Coalinga company owned valuable wells in the San Joaquin valley. It found it could not get a proper tank-car service from the Southern Pacific so as to market its product. Accordingly it spent $800,000 building a pipe line from its wells to tidewater at Monterey."

C. H. SESSIONS, ASSOCIATE EDITOR

FEEDING FAT INTO MILK.

Responding to the popular impression that a rich food will give a milk rich in butterfat, the Farmer's Tribune says:

"We are probably not far from the truth when we state that 90 farmers out of every hundred believe that they can produce rich or poor milk at will from the same cows. Just why this idea has become general, we are unable to say. As a general rule, wherever there is smoke, there is also fire. In other words, a belief that is so general as this one is, namely, that the quality of the feed influences the quality of the milk, has something substantial back of it. This question, however, seems to be an exception to the general rule. Our correspondent may rest assured that he can not to any extent influence the quality of his herd milk. He can increase the quantity by feeding a balanced ration and by giving the cows first class attention in every respect, but he can not increase the quality thereof. At least, such are the conclusions of the experiment stations throughout the United States, as well as in foreign countries, and this question has been tested a great many times at a great many different places under all sorts of conditions. While this doctrine has been preached for years by investigators, their conclusions have had very little effect in changing the public mind on this question. It has been claimed that the reason why the experiment stations did not find that food affects the composition of milk with respect to its fat content was because these stations always experiment with cows under ideal conditions and that, therefore, their conclusions could not be applicable to the average farmer's cow, which is not kept under the most favorable conditions.

For this reason it occurred to the New York (Cornell) station that they would try the experiment on a poorly fed herd and try it on an ordinary farm. This was done, and Wing and Foord of Cornell, who had this work in charge, came to the conclusion, sometime ago, that the fat content of the milk, while they did succeed in increasing it by .25 to one per cent, could not be said to be materially affected by the quality of the food fed. A herd of ten cows was included in this experiment. This herd had practically been starved for years, as the dairyman to whom they belonged was very careless and somewhat short-sighted, in that he did not believe in feeding his cows more than was absolutely necessary to keep them alive. When the station took hold of this herd, the amount of feed was gradually increased until the cows consumed as much of a well balanced ration as they could eat. The total amount of milk produced by this herd was increased in the course of two years by 50 per cent, but the fat content, as stated, was increased only .25 to one per cent. This experiment is the only one we know of that has even showed this much of an increase in the fat content of milk due to the feeding.

The way for our correspondent to increase the amount of fat is to make his cows give more milk and thereby indirectly increase the number of pounds of butter fat. The fact that the fat content of milk can not be increased is one of the strongest arguments in favor of testing a cow's milk before purchasing. Never purchase a cow that gives milk too poor in butter fat to make her profitable for the particular line of dairy work she is expected to do. This does not mean that all dairy cows must necessarily give rich milk."

VALUE IN CONSTANT HABITS IN MILKING.

"It is important how often the cow is milked daily. Some experiments concerning this question have been tried, which show that the more times a day a cow is milked the more and richer the milk she yields. But whether one milks three times or only twice a day, the intervals between the milkings must, as far as possible, be of the same length. The cow is in a very high degree dependent upon habit, and her udder works evenly and regularly. The milking hours, therefore, must be carefully observed, and the same persons must every time, in the same course, milk the same animal. If the milking is begun to late, the cow becomes uneasy, and the tension of the udder causes pain to the animal—in both cases loss of milk ensues. The fact that the quantity of the milk is lessened by milking less frequently and less energetically is a thing of which one avails one's self when wanting to dry a cow. But even in this case it is a bad plan to clean strip the udder; it is by far preferable to milk less often, finally only once every other day, every third day, or more seldom still, till the cow gives so little milk that the milking might be dispensed with altogether. During the biesting period it must be considered not only wrong, but even dangerous often, and hard to milk such cows which show any disposition for milk fever. According to examinations made by a famous Danish veterinary surgeon, this disease is caused by an increased activity in the udder, which must be considered still further increased by energetic milking. But for these two periods, when the cow is being dried and when she gives biestings (first milk), she can scarcely be milked too hard (that is, too often and too energetically.).

"The milker must pay great attention to the cleanly condition of the udder and the teats. If he observes knots or tenderness in the udder, sores on the teats, the milk canal stopped up, or the milk having an unnatural appearance, etc., he must at once tell the foreman. Diseases in udders and teats often being contagious, cows in that way infected must always be milked last, and the milk from the affected part of the udder be put in a special vessel and destroyed, in order to hinder further spreading of the infection. The milk canal in the teat is sometimes very tight (being what is often called hard milked) or often shows an inclination to get stopped up.

"To use a straw, or such like, to widen and 'cleanse' the canal is a very bad policy, because in that way inflamation of the corresponding part of the udder might easily follow. A teat which has a stopped milk canal must first be carefully worked or kneaded between the palms of the hands and then carefully milked clear. A heifer is often sensitive for the milking manipulation, and this sensitiveness will sometimes last until she gets older; in this case, the milker must be still more kind and careful at the milking; and means of restraint or force must be used only in case of great necessity."

A man thinks he knows, but a woman knows better.

Even an electric button won't accomplish much unless it is pushed.

A good dairyman knows his business. He does not chance to have good cows. It is with him a business proposition and he fully understands the necessity of good blood linked together with good feed and care, and also knows the necessity of rearing the heifer calves in such a way that they will be profitable producers. With care and feed there is nothing to hinder the business dairyman from being master of the situation and having conditions favorable to his ambitions. —Farmers' Tribune.

There is a horse for every three persons in the United States.

BE GENTLE WITH COWS.

I have no use for a dog around a dairy farm. One that is properly trained and is looked after by a sensible person may often be useful without being harmful, but where there are a number of individuals looking after the cows, I think the dog should be dispensed with. I have many times noticed a faling off of fully one-half in the quantity of milk given by my cows after they have been given a chase by the dog, while I have in mind a few cases where cows under normal conditions gave six quarts at a milking, would not give a pint after being chased by a dog. Now, a repetition of this experience for a few times may occur even after a lactation period of only three or four months.

Then, as to the matter of striking a cow, I think this is all nonsense. find the cows sometimes become nervous, when I can in no way account for it, and I have known even quiet animals to kick over the milk pail. Now, to rise in your wrath under such circumstances and use the milk stool as a cudgel is simply to give way to temper and only results in permanently spoiling the cow. I have seen men kick a cow with their big leather shoes in order to make her "hoist." Of course, the cow would perhaps kick back, and who could blame her? Two or three experiences of this kind result in her being ready at all times to wage war. Of course, to one who is not interested, there may be a certain amount of entertainment in this proceeding, but the man who is keeping the cows for the profit that is in the business will come out at the small end. By kindness I have often conquered heifers that seemed to be naturally of an evil disposition, while punishment would have permanently ruined them. There is no farm animal quite so nervous as the cow, and none need more careful and more gentle treatment. These are vital points in connection with the dairy business, and cannot be over-emphasized. A good dog is undoubtedly one of the conveniences of a farm, but he should in no case be broken in on the dairy herd. Before giving him an opportunity to drive cows he should thoroughly understand when to stop by the word of his master, otherwise the cows will often be given an injurious chase.

We have never seen an instance where punishing the dairy cow because she made a mistake did any good, and the milk stool has been responsible in the past for drying up as many cows as any other factor which we know anything about. The man who does not know better than to kick or pound a cow has no business on a dairy farm, his place being in a mule barn, where lessons in discipline are given alike by the master and by the animal.

Jersey cows can make profitable use of heavy rations of concentrated food, but their great capacity as producers was not developed upon concentrated foods, but upon grass and roots. While the greatest production is not possible without the aid of concentrated food, it does not follow that the cows of this breed must have a heavy grain ration. It is only necessary to find out by careful study and tests how much grain it pays best to feed. In view of the fact that we raise forage plants such as vetches cheaper than can be done in the East and that grain costs more here than there, is a reasonable inference that the grain ration should be smaller here than there.—American Dairyman.

A PROFITABLE GRADE HERD.

"Last year my father's herd—not a selected lot, mind you, but the heifers from this Holstein cross, produced an average of 309 pounds of fat, or 355.6 pounds of butter, and this year the yield will be increased. The average test of the individual cow is 3.9, the highest 4.9 and the lowest 3.4. The average test of milk produced is 3.75 per cent fat. The largest producers of this breeding is a seven-eighths cow, last year giving 12,008 pounds of 3.4 per cent milk, or 408 lbs. of fat, or 476 pounds of butter. The next highest yield is from a three-fourths cow, which, with 4.5 per cent milk, produces as much fat as the others for the first six months, but is not such a persistent mliker. These are records made on the usual feed and care given the entire herd. In the hands of competent feeders, and by forcing, they doubtless could be made to exceed these figures. In the case of each cow we note that the nearer we approach good breeding, the heavier producer and more presisitent milker, indicating that the more highly improved the blood the better the cow, if care is taken in the selection of males and the proper treatment is given the calves."—Nebraska Dairyman.

PROVIDE SHADE FOR HOGS.

Hogs like sunshine.

Hogs need sunshine, they enjoy it, but there is a limit. To be penned up in a small place on the sheltered side of a barn lot where the sun does double duty and where a breeze cannot pass through is anything but agreeable for the hogs.

Remember that the temperature down in the pen is not what your thermometer shows on the shaded side of a tree. Oh, no. Just get down in the pen, close to mother earth, or the plank floor, and let the sun warm your back a few minutes. A great many pens are made of boards that form a barrier to the breezes. Let the air circulate through the pens. Provide shade with no sides. The hog house makes a shade, to be sure, but it may be anything but cool in there. Some hog pastures need shade. All do that have not got it already. Treat your hogs right and they will do better.—O. J. Farmer.

GEESE NOTES.

Ten geese will consume as much grass as a cow.

Geese seek mates in February.

The gander is a gallant protector.

It is hard to glut the goose market.

Geese, like turkeys, can not be yarded.

The Jews buy only live geese.

The average weight of goose eggs is about five and one-half ounces each.

A goose is said to be the cheapest fowl alive.

A goose is particular about the condition of her food.

A gosling at 3 months of age should dress ten to twelve pounds, depending upon the season of the year hatched, the breed, etc.

TO DRIVE AWAY FLIES.

Mix 2 qts. fish oil, 1 pt crude carbolic acid, 1 oz oil of pennyroyal, 10 oz oil of tar and 1 qt kerosene. Apply with brush, cloth or atomizer and flies will leave immediately. A single application is sufficient for two or three days. This mixture will cost about 85c per gal. and about ½c per day per head. Don't put it on too thick.

HOW TO MILK.

To be a good milker requires patience, gentleness of touch and control over one's self to keep the milking stool where it belongs, no matter what his provocation is to rise up and use it on the cow. In other words, any irritability or harshness of manner that might excite or disturb the animal should be avoided. Do the milking as fast as possible, and without worry. Be thorough, too, in milking to the last drop, for just a little milk carelessly or unintentionally left in the udder will at once begin the work of "drying off" the cow. Regularity in milking, beginning always at the same hour, is another factor that counts, and it makes it easier and less distrubing for the cows if they are milked in the same order every time, as each one knows from habit when to expect her turn.—Farm and Home.

A LICE KILLER.

Drive a stout stake into the ground near where the hogs sleep. Wind with an old rope nailing it well, and saturate the rope twice a week with a mixture of equal parts of lard and kerosene. The hogs will do the rest if there are any lice on them.

THE COW FOR THE FARMER.

The cow for best results with the general farmer, whether it shall be a high-bred pedigreed animal or grade or ordinary scrub is a question which confronts the dairyman or the farmer. Many enthusiasts tie their faith entirely to a pedigree, at least they give undue importance to the matter of pedigree and to name of a strain regardless of conditions or individuality. Others equally as mistaken claim that pedigree is of no value, a thoroughbred is of no more value than any chance animal.

On these points a response to a correspondent in Hoard's Dairyman makes the following points:

"We believe in that cow, without regard to breed, that will return a large dairy profit for feed consumed and at the same time produce calves that are as good or better than herself, when she is mated with the right kind of a sire.

We champion all dairy breeds because in them we find a larger proportion of animals that are returning large profits and produce calves quite equal to themselves.

We believe in all breeds of dairy cattle because they have been bred for generations for the special dairy purpose and have established, with more or less certainty, the power of reproducing dairy function. We are not unmindful of the fact that every dairy breed contains cows that are not profitable to keep and should be slaughtered not only for the benefit of the man who owns them, but for the benefit of the breed to which they belong. Notwithstanding this, the average production of dairy bred cows is much larger than from cows not bred for dairy purposes.

This is the reason we advocate dairy bred animals. It is conceded that through selection such cows can be developed from any breed or kind of cattle; but what is the use of beginning with the beef animal to make a dairy cow when we have a number of good breeds of dairy cattle already well established? It will take a long time to establish the dairy type cow that we want, and when we get her she will hark back for a great many generations to her original ancestors. What would we think of a man who tried to develop a beef strain of cattle from a dairy breed when he could have, already developed, several good beef breeds to commence with? Would he be practical?

It is not our intention to have any one dispose of his cows that he has and go out and buy all pure bred animals, but begin with the cows that he has; select a pure bred sire and select the calves from the best milkers. In time, a thorough bred cow can be purchased, which, with a full blood sire, will form a nucleus for a pure bred herd. It is better to grow into a business than to go into a business."

CORN AND ALFALFA.

The experiments conducted at the New Jersey station show that the average cost per ton of dry alfalfa hay for five years, even with heavy manuring, was but $5.25 and that the feed value of this hay compares favorably with the protein feeds, which at present cost $22 or more a ton. This crop more than any other fulfills that very important requirement, a cheap source of protein for balancing other home grown products. Its growth cannot be too strongly recommended. An ideal situation would be where the farm is growing corn and alfalfa to supply the entire needs of the herd.—Holstein-Friesian Register.

CUTTING AND CURING ALFALFA.

Alfalfa is proving of such value in the East that the utmost care is used in its curing. Its great content of protein is such that it is considered the most valuable hay grown, and to protect from the occasional shower there the farmer goes to the expense of cotton caps for each cock in the field. Cutting out reference to protection from rain, we copy some valuable hints on methods of curing from an eastern paper:

Alfalfa should be cut just as it is beginning to bloom. If the field is fairly uniform the proper stage for cutting is when about one-tenth of the plants are in flower. In dry regions there is no difficulty in curing the hay, but where rains may occur during the haying season great care is necessary to produce well cured hay of good color.

Rains or even heavy dews spoil the color, which, while not making it less nutritious for feed, makes it less valuable for market. The harvesting should take place with as little handling as possible in order to prevent shattering the leaves, which contain a large proportion of the nourishment.

The mower should be started in the morning and the alfalfa put into stacks or the barn as soon as possible. If it cannot be cured in one day, rake up in winrows, or place in small, tall cocks over night. Open them the next morning and draw in as soon as the hay is thoroughly cured.

HEAVY HORSES.

"The difficulties of the hired help question are constantly forcing to the front the question of more and better labor-saving machinery. Large gang plows, wider mowers and reapers, call for more and heavier horses, and the farmers of the great West are finding out that it pays them better to have a few good big draft mares than a lot of light and medium weight stock of the express or 'bus type."—Ex.

To which F. S. & H. replies: "This is all true enough, but how are the kind of horses referred to going to be secured, even from "good big draft mares" if every sire in the land is to be a great big fat hulk, pampered, groomed and doped into beauty of coat and artificially made "style," with never a stroke of work to harden a muscle, strengthen a bone, invigorate a heart or expand a lung?"

CHANGE OF FEED DESIRABLE.

Milk producing foods should be fed to the dairy cow, not fattening foods. A variety should be provided when possible. A change in feed every few days will be quite acceptable to the dairy cow.

To make modeling clay that will stay moist, knead dry clay with glycerine instead of water and it will remain moist for some hours.

VETERINARY DEPARTMENT

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease ap eared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W. J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

FLEAS ON DOGS.

Editor Cultivator: My dog is covered with fleas. How can I get rid of them?—A., city.

Wash with strong suds made of Fels Naptha soap.

Oil of pennyroyal will also drive the insects away. Saturate a rag and bind about dog's neck. Buhach also fixes them.

* * *

GALLED NECK.

Editor Cultivator: Kindly give treatment for galled neck.—B. Y., Dinuba.

Thoroughly wash the affected part with water and castile soap, or, what is better, water with half an ounce of eucamphol to each gallon. Follow by dusting in Squibb's compound alum powder, twice a day. Of course, it goes without saying that the collar should be lifted from the neck as much as possible and the pad kept thoroughly clean by washing each time removed from the neck. Of course, if the case is a bad one, the horse would be relieved from any work.

* * *

VACCINATION FOR HOG CHOLERA

Editor Cultivator: Is vaccination for hog cholera a success? If practicable it would save thousands of hogs in this State alone. I appreciate the value of cleanliness, preventives and remedies generally, but they do not reach as far as they should.—F. J. Fogg, Colton.

Owing to the fact that there are two closely allied diseases often coming together and causing complications which are as hard to reach and yet each caused by separate germs, it has been impossible to perfect a system of vaccination which is successful. These diseases are the genuine hog cholera and the other the swine plague, which is often confused with the cholera. While some parties have claimed to have had some degree of success, on the whole it has proved worthless and we still have to depend upon perfect cleanliness and such remedies as have been discovered.

It is common knowledge that many a herdsman and milker has by his gentle and genuine love for his cows so completely won their confidence that no one else has ever been known to get the same amount of milk that he can.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

GRIT.

About four or five years ago when the editor of the Cultivator invited me to contribute to its columns, in reply to my question, "How often do you want me to write?" he asked, "How long before you will write yourself out?" "I really don't know," I answered, "but it is not like getting married; I can break off at any time and quit writing." The poultry subject is so interesting to me that I fear sometimes our readers may get tired before I quit writing, and I sometimes feel as if I ought to apologize for going over old subjects again and again. I cannot help it, and you will have occasionally to skip a page that may seem unusually tiresome and only remember that there are many beginners in the poultry business, who consult these columns for help or instruction and be patient.

* * *

A very dear old friend of mine said to me, "My daughter says you are running her ranch, and she is succeding beautifully." "Why, I have never seen her ranch!" I exclaimed. "I know it, but she is reading the Cultivator and following your instructions and doing very well, so she calls it your ranch." That is a responsibility that I do not want, but if I can help any one to succeed I am glad of it.

It is a help to hear of the difficulties that others encounter; we all like to hear the story of peronal achievement and it is especially interesting when it depicts the actual doing of things by one who has succeeded. My talk on summer work with hens and also with chickens is just an outline of what I did myself and with perfect success. Others may have good plans and succeed equally well, if they only remember that all animals, human beings as well as fowls, require more green food, vegetables and fruit, in the summer than at any time of the year. It is nature's own way of keeping us all healthy, and if we want to succeed with fowls we must manage to give them a supply of succulent green food. This is easy enough in the East, but not so easy in California, and many a time I have driven on a hot summer's day eight or ten miles to a friend's house to get the tender lawn clippings for my biddies. I kept track of the days when my different friends mowed. I begged some to drop me a postal, and I never went to town without empty gunny sacks in my buggy, and I rarely returned with them empty. I have fed fruit of almost all kinds except oranges and lemons; vegetables of all kinds raw, chopped fine, or cooked; melons, squashes, pumpkins, cucumbers, all with advantage to the fowls during the heated term. Melons, I know, are not considered good by some, but anything that fowls eat with great avidity cannot be very injurious. I observed that the melons loosened the bowels and slightly affected the kidneys, but I thought it helped the moult, and the hens were in vigorous health, I had several express wagon loads of melons and for two weeks the fowls enjoyed them without any ill effects.

Besides green food there is one thing that I have not mentioned lately and that is grit. Few realize the value and the need of good sharp grit. Nature provides a use for every organ of the body, and provides in every body an organ for each specific duty. Most animals are provided with teeth to masticate their food so that it may be prepared for the action of the fluids secreted by the stomach, pancreas and liver. The food besides being crushed by the teeth is acted upon by the saliva in the mouth. Nature has not endowed birds with teeth, but has provided a good substitute in the gizzard. This is a tough, strong muscular organ so situated in the body that all food taken into the mouth must eventually pass through the gizzard. Previous to entering the gizzard the food has been received in a pouch or bag called the crop, where it remains some time. There it is soaked with and acted upon by a fluid secreted in and by this pouch, and a process takes place somewhat similar to the action of the saliva in the mouth of animals with teeth. The food gradually leaves this pouch, passes through the proventriculus, where it is mixed with the gastric juice and is rapidly passed into the gizzard.

The gizzard takes the food that has been softened and mixed with digestive liquids and grinds it by pressing and rubbing it against the small stones that the bird has swallowed. The hardest grains and seeds are ground into a paste which is readily acted upon by the digestive fluids. This paste is pressed onward into the small intestine, where it is mixed with other fluids, and the nutriment is absorbed.

No doubt a bird may be made to exist for a time, perhaps a considerable time, without grit, just as a person may live for years with bad teeth, or perhaps with none at all. We all know how little such people enjoy their food or health, and surely if the birds do not have the means of masticating the food they cannot be healthy, and will not give their owners good returns.

The gizzard is a marvelously strong little mill and when provided with the keep the fowl in good condition. Hard proper grit, or little grindstones, will substances are necessary for grit, such as flint stones, or granite broken up. China, earthenware, glass and such substances broken up make excellent grit. When the grit has not sharp edges the harder parts o fthe food do not get ground up fine enough to be digested, husks and green food accumulate and frequently cause a stoppage between the crop and the gizzard, so that nothing but liquid can pass. Lack of sharp grit brings on diarrhoea, indigestion and liver trouble, the gall overflows and sometimes the gall sack bursts. There are two passages, or openings in the gizzard, one which is much the larger, through which the food enters, the other much smaller,

leading out of it. Thus the gizzard can receive larger substances, but cannot get rid of them until they are ground small, and sharp hard grit is necessary for this. Oyster shells are not hard enough for grit. They are good for laying hens on account of the lime they contain, but are actually injurious to small chicks. Good sharp grit can he purchased at the poultry supply houses advertising in this paper and mills in which you can grind up broken china can be bought at the same places. I used to go to the china stores and get a barrel full of broken crockery for carrying it away years ago when I could not buy grit and found it excellent, in fact, the hens ate it with avidity.

* * *

A friend of mine was very much troubled by her hens laying soft-shelled eggs. At last she persuaded her husband to take his wagon to the hills, where there is a quarry of what she called rotten granite. He brought home a load of it and in few days the hens laid hard shelled eggs. She told me the shells were so hard that the chicks could hardly break out of them.

"I cannot think what ails my fowls," said one lady; "they have all the food they can eat, hut here is another dead."

"Have you ever opened one to discover the trouhle?" I asked.

"Yes, but I never find anything!"

"Well, I think your fowls have indigestion," I said, "hut we will hold a post mortem on this one and try to solve the difficulty."

We found a medium sized gizzard, full of dark earth, no stones, no grit. That told the story, the fowls were starving in the midst of plenty, just for lack of grit to grind their food.

The value of good sharp grit can scarcely he over estimated and yet even intelligent people do not realize this; they think, as did the aforesaid lady, that there is grit enough in the natural soil; this is rarely the case even on free range and when fowls are kept yarded there is never enough unless they are artificially supplied. If you doubt this pound up a broken plate or saucer, the pieces should not be larger than a pea and should have three sharp corners. If your hens need grit you will he surprised to see how eagerly they will eat the china.

Observation taught me that all my best layers were frequent visitors to the grit box. Grit to grind the food, and charcoal to keep it pure whilst it is being ground and digested will help to fill the egg hasket. Give the little chicks the small chick grit.

Eight pounds will be sufficient for the first two months of the life of a hundred little chicks; then they should have a larger size. One hundred pounds of hen sized grit is sufficient to last a hundred hens nearly a year. Pigeons consume in proportion to their size more grit than fowls. If you give your pigeons grit you will keep them healthy.

* * *

EDITOR'S QUESTION BOX.

Bowel Trouble in Chickens.—(B. W.) We have commenced this year to raise chickens and we have lost a great many. We hatched, about one week ago, about a hundred chicks. They have heen fine and healthy, but now they are commencing to die off as the older ones did. The discharges from the howels adhere to the chicken's feathers, giving a dirty appearance. The chicken picks at itself and the others pick at it. We have a medicine, Germazone, which checks the disease, but we dislike to give them medicine constantly. Can you tell what is the matter and what to do? We have been keeping the brooder at about ninety degrees, or thereabouts. Which do you consider most profitable, hens or ducks? What are the properties of millet seed? Is it fattening or relaxing?

Answer.—When chicks show the bowel symptoms you describe up to ten days of age, it is usually caused by their heing poorly hatched, the heat in the machine has been irregular, prohably too hot the last week, or the lamp has gone wrong and the eggs have been chilled. The same symptoms may develop, however, from their being over-heated in the brooder, or chilled, or by their being fed too early in life. Any of these causes will produce almost the same symptoms, which come from the yolk inside the chick not being digested. The reason the yolk does not digest is that the howels are too much weakened by the overheating or the chilling and cannot do their duty. The only thing that may help them is to give them food which is very easily digested. I consider rice hoiled in milk with a little powdered cinnamon added is an excellent food for bowel trouble in little chicks and would advise you to give this. Germazone is good in the water(the copperas is for this trouhle too cold and heavy), a little nux vomica in the water would be hetter, but scalded sweet milk and pure water would be my choice. Do not wash the soiled part. Pick it off with your fingers and grease it with a little carholized vaseline. Be careful not to overheat the hrooder. Give the chicks chopped onion and lettuce every day.

I do not like millet seed for young chicks, it is very hard for them to digest, the seeds are so slippery and hard they do not get soaked up hy the digestive fluids, and when the seeds come to the gizzard they are not ground up unless the chick is very strong and vigorous and its gizzard contains plenty of very sharp grit, otherwise the millet slips through and is voided in the droppings without being digested. This irritates the intestines and the chick does not do well. This is my reason for only giving a little millet and not making it a staple food, also it is quite expensive. It depends upon the market and the facilities of feeding as to which are the more profitable, ducks or hens. I should think you would find hens the more profitable.

* * *

Sick Chickens.—(L. R. T.) My chickens are succumbing to a disease which I am unable to diagnose. They mope around, their combs turn a kind of yellowish red color, and they refuse food. They are about four months old. I feed mash in the morning, Kaffir corn at noon and rolled barley at evening. Plenty of clean, fresh water, grit, charcoal, shade, green onions and other green food. Germozone in drinking water every day. Copperas once a week. Occasionally use sulphur and pepper in mash. Feed lightly morning and noon hut give all chicks will eat at evening. Can chickens be raised successfully at sea coast towns, say two miles from ocean?

Answer.—Your chickens have symptoms of liver trouble and lice. I should guess from your letter that they do not have sufficient green food and they have indigestion. Germozone is very good for roup but should not he given for indigestion nor should it be given every day. Give a medicine for a week if necessary and then either rest or change it. Give a little Epsom salts in the drinking water for two days then give Nux vomica about forty drops in a quart of water, not giving any other water. Are you giving any animal food? Or what are you giving to cause indigestion? Have you made any port mortem examination? What did you discover? If it is difficult for you to diagnose the case on the spot when you know all the conditions, how much more perplexing for me! You do not mention the breed, nor if they are on free range, nor how they are housed, nor the ingredients of the mash. I know the comh turning yellow is a strong symptom of liver trouble and indigestion, hut I do not know enough about your care of them to he able to tell you where you are lacking.

Chickens can he and are heing raised very successfully near the sea coast. They may require a little different handling at some places, but with sanitary conditions and care they can be made profitahle almost anywhere.

CURING COLDS.

Each fowl showing evidence of cold or congestion is shut up in a small coop and given two grains of calomel at night, followed hy a one-grain quinine pill night and morning for two or three days. If there is any discharge from nostrils, a few drops of camphorated oil are injected into each nostril. If any improvement is manifest in two or three days they are removed to a small room and a solution of copperas added to the drinking water. They are kept here for a week or two, or until they show a complete recovery. If, on the other hand, after two or three days observation and treatment no improvement is manifested, the hird is killed and huried.—American Agriculturist.

White Leghorn Chicks, 7½c
Reduced price after June 1st. These chicks are bred from superior, thoroughbred, vigorous stock. Excellent all the year layers of large white eggs.
White Plymouth Rock Chicks, 12½c
Hatching done, 3½ cents per egg.

WARNING!!
THE JUBILEE INCUBATOR CO.
now of Oakland, California beg to announce the removal of their factory and business to SUNNYVALE, SANTA CLARA COUNTY, CALIF., 40 miles south from San Francisco, where a large plant is being constructed.
The Jubilee will possess the finest works and most splendid facilities to be found in the West, and also ample room for further expansion.
This move is of the utmost importance to every Poultryman on this Coast. "The Why and the Wherefore" is fully explained in the **JUBILEE ANNOUNCEMENT.** If you have one chicken or 5,000 you should have that Announcement.
You are no doubt curious to know **why** we moved to **Sunnyvale,** and where **you** will be benefited, Get the **Announcement.** We mail it free. Now get it,—we promise you it will be interesting.
TAKE NOTICE, On and after Aug. 1st our address will be
SUNNYVALE Santa Clara County **CALIFORNIA**
Until then, the same as for many years:
JUBILEE INCUBATOR CO.

SUMMER HATCHING.

While the belief in summer hatching is not general, it has some strong advocates in California. Of these J. L. Harrison, of Lave Avenue Poultry Yards, Pasadena, by our own request, gives his ideas and reasons for them and we give below for the benefit of our readers. Sure it is that Mr. Harrison makes strong points and worthy of consideration.

"Noting your inquiry of recent date, I will state that I have found summer hatching very profitable. Given the requisite shade, water, green feed and clean quarters, July hatched chickens have afforded me the maximum of profit. Contrary to the general impression, summer hatched chicks live and grow with a smaller death rate than those hatched from January to April. Dirty houses and runs, together with a lack of interest or enthusiasm on part of the care-taker will cause a failure that my be wrongly charged to the hot weather or to the old notion that poultry does not do well in California. Over crowded yards is another cause of failure.

The bulk of my breeding stock is raised in April, May and June. My prize winners at the last Los Angeles show were June hatched birds and were in far better plumage than those I hatched earlier in the season. Theo. Hewes, in the last Inland Poultry Journal, claims that summer hatching is a necessity in parti-colored birds, the colors of the late hatched being invariably better than the earlier ones. This claim is substantiated by many of the eastern breeders and works out all right in this State, where conditions are supposed to be different.

Theoretical balanced rations should be avoided at any time and especially during the heated months. By using common sense methods of feeding it is possible to secure better developed birds at six months than at eight or nine months by a miscellaneous mixture of feeds misnamed balanced rations. Given cracked corn, beef scraps at all times and green feed once a day, a chicken can balance its own ration to a nicety and I will guarantee better growth than can be produced with any conglomeration of seventeen or twenty-seven kinds of seeds and grains now on the market. This bill of fare should be continuous from the first feed until the cockerels are marketed and the pullets moved to the laying pens. The cracked corn for the first two or three weeks should be finely cracked, and if this can not be readily found, common feed meal will answer. Pullets raised by this method ought to be laying in four and a half to six months and I have cockerels that weighed over four pounds at three months.

September and October hatching is more difficult than July and August, owing to the scarcity of eggs and the lower fertility. I have noted a steady decline in the fertility from the first of July to the middle of October, the eggs being much weaker later in the moult.

An incubator lot placed in the machine August 15 tested out 70 per cent fertile, those started two weeks later tested 60 per cent, while a machine started Oct. 15th, tested out one-half. The chicks hatched in October and November are apt to suffer from the early rains and a chick once stunted either by chill or an excess of lice should be given an early burial. I have found the smallest percentage of profit to be in hatching from September 15 to February 1. The pullets raised between these dates lay a few eggs and then take a moult along with the older stock.

The broiler business is something like growing hot house cucumbers. It requires an expensive equipment, plenty of experience and last, but not least, a market. There are people in California who are willing to pay Philadelphia and New York prices for correctly grown broilers, but these people are not as numerous as the customers who want broilers at the pound price of old hens. I am convinced that there is nothing in the broiler business for the average mortal. Cull and surplus cockerels must be disposed of at some price, and I have noticed an advance in the quotations after Thankgiving for the past three years. Summer hatched cockerels should be marketed for the Christmas market or later, and the prices per pound will average two to five cents higher than the November market.—J. L. Harrison, Lake Avenue Poultry Yards, Pasadena.

HOW TO CLEAN EGGS.

The proper cleaning and sorting of the egg crop, so that it will have a neat and attractive appearance will add much to its selling qualities. Like everything else, there is a best way for doing this.

Eggs all one color and perfectly clean make an attractive appearance and will readily bring several cents more per dozen than a dirty lot, particularly when quality goes with appearance; and the one is generally an indication of the other. An egg is improperly cleaned when it is wet too much and not rubbed dry with a dry cloth. Some when they see spots of dirt on eggs put them in a pan of water and wash them like potatoes. There is on the freshly laid egg a mucilaginous covering which gives it a velvety appearance peculiar to new eggs. Water removes this, making the egg have an older appearance, and destroys its keeping qualities, as this covering makes the shell impervious to air. An egg, then, if it is not much soiled, should merely be moistened where necessary and rubbed dry. If the blemish is in the nature of a stain, a little powdered scouring brick will help, and if this is not effective vinegar may be used in addition. In this way any stains may be removed from an egg. Sometimes they have to be put in water, but do not do it unless it is necessary, and then rub dry afterwards. If this is not done they will look soiled and dingy. Eggs should be collected three or four times a day.

Regularity is an important rule in the care of fowls.

A vacation is due. Take it.

CHARCOAL FOR HOGS.

The economical and satisfactory way of securing a good supply of charcoal for hogs is thus given by the Iowa Homestead:

Where one has a supply of corn cobs it is not a difficult matter to make up a batch of charcoal. Dig a pit sufficiently large to hold the amount of cobs to be used at one burning. Usually this pit is circular and may be made four or five feet deep. However, we have had good success in using a trench about two feet wide, four feet deep and any length.

Start a fire with shavings and kindling in the bottom of this trench and gradually pile on the cobs. Care must be taken not to smother the fire—just allow the flame to show through the surface all the time until the pit is full, then place a tight covering over the top. Wood will not do, as it will burn out. It generally pays to have on hand for this purpose an old piece of sheet metal of some kind. Build a little earth around the edges so as to absolutely exclude the air.

When the charcoal has cooled off it may be sacked up, and usually it is advisable to mix with it a little salt. A mixture composed of one barrel of charcoal to one pail of salt is usually eaten eagerly by hogs. Where it is desirable to use such a mixture for the prevention of worms, a little copper sulphate may be dissolved in water and then sprinkled on this mixture so as to cause its uniform distribution. The whole mixture is usually placed where hogs may have access to it at all times. It is not difficult to extemporize a self-feeder so that the mixture is kept dry.

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock aud Eggs sold under absolute guarantees.

PAJARO VALLEY AND ITS APPLE INDUSTRY.

(Continuep from First Page.)

apples, though the product is of excellent quality ,are not raised to any extent because they ripen when the markets are glutted with other summer fruits, and consequently prices are not remunerative.

Red varities are not planted extensively, as the demand on this coast is limited and exhorbitant freight rates preclude the shipment of these to eastern and European markets in competition with the eastern grown red apple.

The two varieites which attain the highest perfection, are most sought after and command the highest prices, are the Newtown Pippin and the Bellflower. During the last ten years these two have been planted almost exclusively.

These two varieties are quite exacting in their requirements, so much so that the known area in which they can be profitably produced is limited to a very few localities on the globe. This fact, together with their popularity amongst consumers, will always insure for them a place amongst the foremost in list prices in any market.

* * *

Growth of Industry.—During the first twenty-five years after the settlement of Pajaro by the Americans, the apple increased but little. Sufficient quantities of apples to supply the coast markets were being raised in other parts of the State, principally in the counties adjacent to San Francisco bay, and as the demand was limited, there was no special incentive to plant commercial orchards in this district.

In 1873-4 two of the apple grower's most dreaded pests, codling moth and San Jose scale, made their appearance in California orchards. Mainly through negligence on the part of growers, such havoc was created by these insects that by 1880 the industry was practically abandoned in what had been the foremost districts of the State. As a result of the calamity which befell those sections, together with consequent stimulated demand at high prices, our apples first came into prominence and the business received that impulse which afterward transformed Pajaro valley into the leading apple producing district of the West. Our climatic conditions proved not so favorable for the rapid multiplication of the above named pests and the loss to the orchardist from this source was very slight for many years.

At present the number of apple trees in this ditrict reaches close to 900,000, and the area covered exceeds 12,000 acres. Approximately seven-eighths of these trees are Newtown Pippins and Bellflowers in about the proportion of three of the first to two of the latter. The remainder is made up of every variety found in the catalogue, with White Winter Pearmain, Red Pearmain, Missouri Pippin, Sangford Seedling and Lawver predominating. From present prospects the yield this season will amount to 1,750,000 boxes, or about 2700 carloads.

But slightly more than one-third of the trees have attained full bearing. Figuring on the rapid increase in yield of the large acreages which are just reaching the bearing age, the Pajaro apple output within the next five years will amount to upwards of 5,000,000 boxes.

* * *

Markets.—The Newtown Pippin, on account of its superior keeping qualities, may be sent to the most remote parts of the globe. It finds best markets in Europe and the eastern States, but there is a growing demand in Australia, Asia, South America and islands of the Pacific.

Markets for the Bellflower are confined mainly to the territory reaching from this coast to Chicago, although the demand is gradually extending eastward from the last named place.

The poorer grades of apples are shipped to markets within the State, or are used for canning, jams, jellies, cider, vinegar and the dried product.

Though Pajaro can produce Newtown Pippins and Bellflowers which can not be excelled by any spot on earth, yet through an unfortunate combination of circumstances, the reputation of our fruit has suffered materially during recent years. Some of the misfortunes came through causes which could not be obviated, others are due to avarice and shortsightedness on the part of some of those most interested.

Last season, shortly before picking time, an unprecedented hot spell prevailed for a day or two. The resultant injury to the apples shipped out was not perceptible until the fruit arrived at its destination in distant markets. It rapidly deteriorated, much to our discredit, but too late to remedy the evil consequences to the reputation of our apples. Again, the greater portion of the apples have been handled by packers who buy the fruit on the tree, paying a lump sum for the crop. Prices range pretty high in that event, the packer paying from one hundred to two hundred dollars per acre, depending upon variety and prospective yield. After paying a high price and with the whole crop, good and bad, on his hands, the temptation to the packer is very great to smuggle inferior fruit into the boxes marked "choice."

Particularly would this inferior pack be expected when brokers and buyers from outside markets "wink" at the deception and accept the pack because they can get the goods at a few cents cheaper on the box than they would have to pay for choice apples.

There are reliable packers in Watsonville, and if outside buyers would deal only with those who put out honestly packed goods, the unscrupulous packer would soon be eliminated.

* * *

Manner of Packing.—Very few orchardists pack their own fruit. The growing tendency is to handle on a plan somewhat similar to that of the fruit exchanges. In this case reliable men have established large packing houses in town at convenient places for shipping. The orchardist delivers his crop at this place in boxes, loose. From this time the packer takes charge of the fruit, furnishing labor and material for packing and also finding a market for the product. These houses are send-out a strictly reliable pack and the plan is proving satisfactory to all concerned.

Apples are packed in pine boxes 10x11x22 inches in dimensions and a box holds about fifty pounds. For export, each apple is wrapped in paper. The grade is determined by the number of rows or tiers required to fill the end of a box. Grades are known as 3, 3½, 4, 4½ and 5 tier. The 4-tier is in greatest demand and prices are quoted on a 4-tier basis. Prices for 4-tier Newtown Pippins and Bellflowers range from about 90c to $1.15 per box f. o. b. Watsonville.

While the apple orchard does not reflect all sunshine and profit, yet all things considered, there probably is no fruit industry of the State attended with as little annoyance and risk and no branch of fruit growing more pleasant to pursue nor yielding as sure profit as the apple business in Pajaro valley.

A GOOD PUMP.

The installation of a deep well pump for the Del Monte Irrigation company of Pomona (the largest irrigation company in that locality) marks a change in the manner of raising water heretofore employed by that company.

Up to this time it has used a steam driven air compressor of 125 horse power, at a central station, pumping several wells at various distances from the central plant. While the plan was feasible at the time it was installed, the water level in the wells in the vicinity during the last few years has receded so far from the surface that the air lift ceased to be economical and raising water by this means was too expensive and no longer profitable for the stockholders.

In looking for a means to overcome this difficulty, the engineers and directors, after a thorough investigation of all the different types of pumps, and after calling for bids from all the different manufacturers and agents in this part of the State, purchased a plant of the Pomona Manufacturing Company, of Pomona, consisting of their No. 28 double acting power head, used in connection with a ten-inch, double acting Pomona cylinder and valves. This plant is being driven by a 20-horse power electric motor and is raising 47½ miner's inches of water at a cost of 29 cents per hour for power, showing an actual efficiency on the pump of 72 per cent.

This plant was finished and made its trial run on June 10th. The directors of the company were so pleased with the plant that they accepted it at once, as it was doing its work easily and raising 20 per cent more water than the contract called for.

Another plant put in for the combined Orange Grove Tract Water Company and Packard Water Company, near Pomona, is raising 48 miner's inches of water 100 feet on a fuel consumption of 2 gallons per hour, making the cost for power 11 cents per hour.

The Pomona Manufacturing company have had phenomenal success with their new and improved deep well pump, having put in 90 per cent of the deep well pumps in the vicinity of Pomona, besides several at Cucamonga, Lindsay, Ventura and Los Angeles.

Any one interested in deep well pumping should send for their new catalogue, which will be sent free on request.

WILL ENLARGE.

The Western Gas Engine Co., of Los Angeles, has just purchased eight acres of land on the corner of Santa Fe and Slauson avenues for which was paid $50,000. This property is to be used for manufacturing purposes and it is anticipated that the Western people will soon begin the erection of a vastly improved manufacturing plant for the purpose of putting out their popular Western gas engines. It is rumored there may be an increase in the capital stock to provide for these extensions.

The Western people have had pronounced success in their manufacturing business, especially along the line of the gas engines which are largely used as power for pumping in many parts of the State. They will probably require several months to complete the improvements before transferring entirely from the old plant, which is now located on North Main street.

Queries and Suggestions

PLANTING EUCALYPTS.

Editor Cultivator: I wish to know how and when to plant eucalyptus seed. I expect to set out groves of both blue and red gum next March. Our winter climate here (upper Sacramento valley) is about the same as Los Angeles, only we have frosty mornings and people claim that home grown trees do better than those from the South. Have been unable to find any one who can tell me how to plant the seed or care for the trees after they come up—prior to time of transplanting.—N. A. Chisholm, Jacinto.

The time for planting the seed is during the months of August and September. The seed may be broadcasted in nursery trays in good, rich, friable soil. When plants are one to two inches high, transplant in same size trays, one hundred to the tray. One point which will have to be guarded against at time of planting is to prevent ants from carrying away the seed. This may be done by surrounding the seed trays with a line of buhach or by a line of tanglefoot or some sticky substance which will prevent them from gaining access to the seed.

Of course, it goes without saying that care must be exercised to prevent drying out of the seed trays and a better stand will probably be securd if protection from heat of midday sun is given by lath or with canvas cloth a few inches above the surface of the soil.

* * *

CRACKED PRUNES.

A subscriber at Santa Rosa writes stating that the crop of prunes thereabouts will not be more than half a crop and fears that even of these many will be injured by cracking or splitting open. Many of these often split open clear to the seed. He wishes to know cause and whether he can prevent it. Soil is aparently the same as in surrounding orchards where there is little or no splitting.

This is the first we have heard of a case existing like this. That is, of one orchard being very bad and others showing but little if any of this trouble. It is usually claimed to be caused by the condition of the atmosphere. That is, a moist, humid atmosphere causing the trouble while a drier condition leaves the fruit exempt. Why one orchard should show it worse than another we are unable to say. So far as we have heard, there is no treatment for this trouble other than that the moist condition of atmosphere be changed for a drier condition. This, we understand, has occurred to the queen's taste in all sections of the State since our inquirer sent his request for information. There will probable be no more splitting of prunes this season.

* * *

MARKET QUOTATIONS.

Editor Cultivator:—In your market quotations are the prices quoted those which the wholesale men would pay us if we should ship to them, minus the commission? Or are they the wholesale price to the retail trade? To illustrate: Onions, silver skins, 60@75" means that they are from 60 to 75 per 100 lbs. "Cabbage, per sack, 25@40." What constitutes a sack; is it a sack used for sacking grain and are they sewed up like a sack of grain or are they gathered and tied up?

"Bell Peppers, 15@20" means per lb., does it not? Cucumbers, per crate, 75@1.00. Does a crate of cucumbers, tomatoes, etc., weigh the same, and what is the weight? Also, "Rhubarb, per box, 40." What does a box weigh? Also, peaches, apricots and figs, per box; what is the weight of a box? Cantaloupes (San Francisco market) per crate, small, 50@60." How large is the small crate, and also the large?

Tomatoes are quoted per box or crate, $1.25@1.75. Are they the same size? Also in shipping bell peppers, green, what would be the best way to ship, per box or crate?

We bought some onion seed and it was very badly mixed. We would like to obtain some of the very best Australian Brown, Prize Taker, New Queen, W. Bermuda. We hope that perhaps some of the readers of the paper will know where we can obtain first-class seed.

Where may I sell broom corn?—Subscriber, Yuma.

The prices quoted under either Los Angeles or San Francisco are those paid to producers so far as we can secure them. That is, as you say, less the commission. The Los Angeles markets are corrected each week by various firms at the Los Angeles market, corner Third and Central avenue. Where 60c is the selling price to wholesalers in a sack of onions, the 60 cents, less freight and commission, is paid to the producer of the onions. So it is in one sense, wholesale price to the retail trade, also price to the producer.

"Cabbage per sack" means a common barley sack filled "considerably more than full." That is, the cabbages are packed in as tight as possible even with and even above the top of the sack, the sides of the sack remaining perfectly straight, being no opportunity for gathering together and tying or even sewing together as with grain. Then the sacking twine is used to draw over the top of the protruding cabbages, which bulge far beyond the edges of the sacks and thus hold the cabbages in, the twine being woven back and forth for that purpose.

As to the weight of the sack, it would be impossible to say, for it depends upon the solidity of the heads. Therein comes the variation in quotation. That is, a "light" sack would probably be filled with cabbages not filled out and firm, consequently would sell for the lower quotation, namely, 25 cents, while a sack of solid heads would readily command the 40 cents.

Bell peppers, .15 to .20, or more correctly .15 to .18 as it is this week, means per pound, and the best way to market them is simply to sew up in barley sacks and ship to market. These are also filled very full so that the stuff may readily be seen through the open end of the sack. Of course this is not a vital factor, because of the fact that they are sold by actual weight.

Cucumbers are quoted early in the season by the dozen, going as high in midwinter as $1.50 a dozen. Later they are quoted by the "crate" which, during the high prices, means the ordinary twenty pound fruit crate. Later as they become more plentiful a "crate" means a thirty pound picking box.

Here we may mention that there are two general sizes of crates in which fruit is marketed. The larger of these has an inside measure of six inches deep by fourteen by sixteen and a half with cleats across the top of the end. This is sometimes called the thirty pound orchard picking box and when all fruit is cheap it is quoted in this size picking box. When it is high priced and scarcer, it is usually quoted by the twenty pound crate which is a little smaller box four and a half inches deep, eleven and a half by eighteen and a half inside measure. This size crate has no cleat across the top but usually has cover nailed on. For grapes these are filled with four "baskets" each supposed to contain about five pounds. Therefore cucumbers from now on through the season will be quoted by the larger or thirty pound fruit crate.

"Rhubarb per box" means a box about the size of the ordinary apple box, which will contain about forty pounds as ordinarily packed. This, at present quotations, would mean the rhubarb is about one cent per pound. Cantaloupes, when quoted per "small crate," or "special," means the size of crate which will hold about sixteen of average sized cantaloupes. "Ponies" hold fifty-four of the same size melons, and another sized crate, slightly smaller than the ponies, holds forty-five melons. Tomatoes, like other products, are usually quoted in the twenty pound box, but now, as they are becoming rather more plentiful, often appear in the thirty pound picking box. The wide range which usually prevails in the quotations of tomatoes is not because of the difference in size of boxes but because of the great difference in quality. There is often a difference of more than fifty per cent in price of two boxes of tomatoes, caused by smooth, even-sized, ripe fruit on the one hand, and a conglomerate mess of green, ripe, various-sized fruit on the other.

GREEN FRUIT SHIPMENTS.

"One of the greatest years for green fruit shipments in the history of the State" is the present estimate of conservative fruit shippers. This is contrary to the earlier season estimates for the shortage of cherries was so exceedingly great that it was feared the entire season would be most disappointing. In this respect it is, of course, to be regretted that cherries are the most valuable output of the State in the matter of fruits and represent the greatest value per car. For instance, two cars shiped this year from San Jose realized a total of $5342 for one, and $5156 for the other. These are said to be the highest prices ever obtained for green fruits of any kind. Besides that, cherries made the record sale at the opening of the season of $100 per box, or $10 per pound, which was, of course, paid for advertising purposes.

The total number of cars of cherries shipped this year was, up to the end of June, 78¼ cars. This, not considering price, is not a good showing for last year 207 cars were shipped up to the same date, and the year before 208¾ cars. But with other deciduous fruits, this showing is entirely changed. For instance, apricots this year, 279 cars; last year, 93 cars, the year before 222½; peaches, 284 cars; last year 93¾, the year before 128½; plums make the biggest gain, however, showing a grand total of shipments up to June 30th of 542, as against 118 last year and 224 the year before. Notwithstanding the fear that the pear output of the State was wiped out by the blight, the shipments this year nearly doubled those of last year, being four cars as gainst 2½ last year and 2¾ the year before. Of course, the pear season is not yet fairly on.

Predictions of some shippers are that the total output of table grapes this year will be from 2000 to 2500 carloads. Last year's output was 1395 while that of the year prior was 1785 and that of 1902 1017 cars.

These statements give color to the claim of some that a total income to the State this year from green fruit shipments will exceed that of any other year.

Apple Land For Sale

Elevation, 2500 ft.; Acres, 800; Price, $17,000
None better in all California. Foothill land, part level, part rolling. Soil, deep disintegrated granite. Water, abundance can be developed. Address

PLANTING A TREE.

What does he who plants a tree?
He plants a friend of sun and sky;
He plants a flag of breezes free;
The shaft of beauty towering high;
He plants a home to heaven anigh
For song and mother-croon of bird,
In hushed and happy twilight heard—
The treble of heaven's harmony—
These things he plants who plants a tree.

What does he plant who plants a tree?
He plants cool shade and tender rain,
And seed and bud of days to be,
And years that fade and flush again;
He plants the glory of the plain;
He plants the forest's heritage;
The harvest of the coming age;
The joy that unborn eyes shall see—
These things he plants who plants a tree.

What does he plant who plants a tree?
He plants, in sap and leaves and wood
In love of home and loyalty,
And far-cast thought, of civil good—
His blessing on the neighborhood,
Who in the hollow of his hand
Holds all the growth of all our land—
A nation's growth from sea to sea
Stirs in his heart who plants a tree.

Richard Watson Gilder.

A Mental Catastrophe.

"I was perfectly sure I had never seen the place before. So far as I could make out by the aid of a single light which burned above me. Suddenly, without any volition whatsover on my part, I found myself to be in what appeared to to my inexperienced eyes a kind of subterranean passage from which I could discover no possible means of exit.

I suppose it did not really matter, since there seemed to be no way out of what was fast becoming to me like my preconceived notions of the infernal regions, but it did not serve to add anything to my grim enjoyment of the novel situation to find that I was held fast in some sort of greenish colored seat placed hard against a solid wall of slate or stone. I refer to the color because, although green, I believe is said to have a particularly cooling effect upon the eye, I have a strong aversion to it, and the mere sight of it, even upon an ordinary occasion, except in the adornment of nature, is alone sufficient to produce a most disagreeable impression upon me.

However, this I decided was no ordinary occasion; and my unpleasant sensations were further augmented by transitory appearances of a hideous grinning female, who was also garbed in green.

My first cheering thought was that, without a doubt, I was about to pay the death penalty in the electric chair for what was to me as yet an unknown crime. But this idea was quickly routed by the discovery of a third person in the weird place, who seemed to be taking perfectly fiendish joy in flourishing all sorts of terrible looking instruments about my head and face.

Listening intently I could hear him laugh in almost noiseless diabolical glee, and heard him say distinctly, "More yet to come," when I found to my intense horror, after a twinge of pain sharper than any I had ever before in all my life experienced, that my head had been closely severed from my body, and was lying on a stand close by. And as if that were not enough, this remark of his further enlightened me that I had suddenly become a kind of hydra-headed monster, with no one knew how many heads to cut off. That my tornemtor was bent on having them all was proved by another horrible twinge of pain, and the gratifying sight of another of my heads lying neatly alongside the other.

Like an inspiration a thought came to me. When one is in such a predicament as I was he or she will most surely clutch at the proverbial straw. What I had not before noticed was a huge phial of some colorless liquid within reaching distance of my left hand. It was labeled, chemical fashion, in symbols, but what it really was I could not determine. Still it was not to be wondered at that I should have found my mental apparatus somewhat impaired and my knowledge of the sciences rather hazy after the loss of so many heads.

Dominated all the while by the thought that it might fortunately prove to be some acid that would put out the eyes of my dreadful assailant, and so prevent him from severing my last head, should any happily remain, I made one gigantic effort and threw it with all possible force. I suppose my aim was not true. At any rate, I missed him! Still it was some sort of satisfaction to know that a goodly portion of it landed upon the hated grinning female, the sight of whom I so detested.

I found syself dimly wondering what would happen next, when I looked up and saw the kindly face and twinkling eyes of my father-in-law, still holding in his hand a pair of shining forceps, while on a small table close beside me—they were all there, biscupids, and molars—all those teeth that for months past had been bothering me so.

"Didn't give you quite enough gas, did I? Felt it some, eh, John?

"But a deuce of a mess you've made of your wife's gown." He smiled genially.

"Yes," chimed in my wife, "here I've been wanting a new dress all the spring and you declaring you could not afford it, when you must needs go and take gas for all those horrid teeth to be out, then say and do all sorts of funny things, the last of which is to throw acid on my best gown, so that a new one for Easter is now a positive necessity."

But I had no word of complaint to offer, so overjoyed was I to find those wretched teeth were out and that same and only head on my shoulders, just where it had always been, showing no present signs of decapitation.—Boston Post.

One man makes a road, and another walks on it.

He—But what does your father see in me to object to? She—He doesn't see anything in you. That's why he objects.

HOMELY HINTS.

Ironing Hints.—The doing up of fine underlinen is far more important in these days than ironing a shirt, and a good living awaits the woman who cares to learn this art and practice it in the cities. When these articles are washed and dried the ruffles and trimming should be dipped into weak starch and rolled down tightly, keeping all starched and fine portions inside. Iron in about an hour.

First of all, iron the sleeves, then the ruffles first, and then the body part. Any crimping or fluting must be done last of all, after slightly dampening the ruffles over again. When ironing circular ruffles always iron "with the thread" of the goods and the ruffles will not sag.

For white skirts and for dresses, a skirt board is a necessity; it should be about fifteen inches wide at the bottom and narrow down toward the top to about nine inches, and should be about five or five and a half feet in length. It is much better to purchase the folding skirt boards, being less expensive than having a carpenter make one.

Cover first with an old blanket, folded double, and then with a length of white muslin. Tack the blanket into place underneath, but merely pin the muslin cover to the blanket.

By pinning this very closely together the pins will hold the muslin cover smooth, and it is an easy matter to change it every week.

If one doubles a petticoat from front to back, in order to save labor, always smooth the front, or iron only to the fold; then open the skirt and smooth the front, as leaving this fold in is apt to make the skirt stick out in front when it is worn.

A very little board, long and narrow, with a pointed end, is useful for ironing shirt waist sleeves, shirt bosoms and many small places in children's garments, and this can be easily made at home and covered.

Sheets are generally ironed double, and they should be folded lengthwise, for this is exactly opposite to the way they are hung upon a line; it distributes wear and makes them last longer.

* * *

Chloride of lime should be used about the house and outbuildings during the summer. It will drive rats out of the cellar at any time of the year, and in summer its use about a house will do much to keep away flies.

If the cover of a fruit jar sticks, do not attempt to wrench it off; simply invert the jar and place the top in hot water for a minute. Then try it, and you will find it turns easily.

HOW LONG A BRIDE.

A woman may know that she has ceased to be a bride only:

When she finds herself saying uncomplimentary things to her husband.

The first time her husband criticises her frocks.

When he grows economical with his kisses.

When she begins to nag.

When he becomes sarcastic about the food.

When she does not mind coming to breakfast in curl papers.

When he tells her how pretty some other woman looks.

When a meal becomes so quiet that she can plan a whole frouck between the courses.

When he begins to go out to his club.

When she begins to hunt up her old friends and enjoy calling on them.

DON'T BE SHIFTLESS.

Don't get into a shiftless habit of reading or thinking, or doing things. Keep snugged up in your mind and habits. Get into the habit of being prompt with your work and in paying your debts. Don't acquire the loose, helter skelter, shiftless way of looking at things and doing things. If you are shiftless, you will be poor. There is no help for it, you will be poor. Poverty invariably follows shiftlessness. It is the man who is orderly, neat and snug about his farm work that keeps control of his work. Shiftlessness of habit comes from having a loose, untrained and unorganized mind. "As a man thinketh in his heart, so is he."—Country Gentleman.

THE CHERRY TREE WAS A CHESTNUT.

George Washington—"Mistress Curtis, Martha, I love you! I would tell you the old, old story. I—"

The Widow Curtis—"Oh, George, please spare me that cherry-tree incident."—Woman's Home Companion.

AN UNFAILING SIGN.

"Doctor," queried the inquisitive person, " do you believe that the cigarette habit causes weak minds?"

"Not necessarily," replied the M. D. "As a rule it merely indcates them."

THE STAR OIL BURNER
ITS OWN GAS MAKER
(Patentees N. L. Rigby and S. S. Sprague
This Burner is offered to the public upon its merits. It is not an experiment, but a practically tested and successful invention. It has no superior for safety, simplicity, economy and durability. It is made without bolts, screws or rivets. It makes a pure dydro-carbon gas from low grade distillate oils, and gives you a fire as bright as the stars. Free from soot and smoke.

A HOUSE-CLEANING SONG.

Can you sing? Then sing
A house-cleaning song,
To make the house ring
When tempers go wrong;
Sing something bright,
Or say something funny,
For all will go right
When tempers are sunny.

Don't wear your worst gown,
Or tie up your head;
Don't carry a frown—
A picture to dread;
House-cleaning is fun
If taken that way,
So let in the sun
And be merry and gay.

One room at a time—
Be not in a hurry;
Do not repine,
Nor get in a worry.
Scrub just as you please,
And in your own way—
It's nothing to you
What the neighbors may say.

Have a dinner that's nice,
And take time to eat—
To starve the whole household
Will not make them neat;
Have a good time,
Instead of a fit—
I'm penning this rhyme
While resting a bit.

—Annie A. Preston.

AN ESSAY ON GRUMBLING.

Your grumbler never gets on. Nature in a sarcastic mood seems to have ordained that the persistent whiner shall want for everything except something to whine about.

The whine is a signal call to a thousand and one little demons of distress and disaster, which mock and lash, hinder and dishearten.

There is nothing else you can look for with so much certainty of finding it as trouble.

But have you never noticed that most of your troubles are of tomorrow, that few of them are really present today, that there are hardly any worth mentioning in all your past?

If anticipation did not go more than half way to meet troubles most of them might miss their way and never get near you.

He who whines does himself injury such as his meanest enemy could not do to him if he would. He warps his own mind; he weakens his own arm; he enervates his own strength; he deadens within himself the divine gifts of cheer and hope, and he dams up his own soul against the sweet insiprations of human sympathy.

Never yet did success worthy of the name abide with a man with a whine in his heart.

A whine is premeditated and prearranged failure.

A whining voice means a whining character. It is a mark of weakness too inexcusable even to excite pity. The broadest charity shrinks and draws back the hand at sound of a human whine—a sound more disgusting and dismaying than the hiss of a snake.

They say that one of the things you can not make or alter is environment—that it is fixed, inflexible, and that you are its slave. This is a pessimistic lie.

To our own moods environment is a looking glass; it smiles back at us if we smile; if we frown, it frowns.

He who thinks the world is full of good people and kindly blessings is much richer than he who thinks the contrary. Each man's imagination largely peoples the world for himself. Some live in a world peopled with princes of the royal blood; some in a world of paupers and privation. You have your choice.

This is a big, busy world. It cares precious little what you think of it or what faults or troubles you find in it. It is a choice that concerns yourself more than all others combined, whether you grouch in the gloom, the companion of hateful goblins, or stride in the sunshine, seeing smiles and catching shreds of song.

Men and women in God's image were not made as whining, groveling things. They are made to stand erect, mentally as well as physically; to labor well and joyously; to take the gifts of Providence, whether they be joy or sorrow, and bear them cheerfully and with courage; to add ever something to the world's store of happiness, if it be only a smile.

If you would win anything, do anything, be anything, don't whine.

LAMPS.

Every good housekeeper takes pride in caring for her lamps and keeping them in the best possible condition. Lamp flues can be hardened and rendered less likely to break by putting them in a pailful of cold water, and allowing it to heat gradually. Boil them ten minutes, cool slowly and they will be ready for use. A little hay or straw should be put in the bottom of the pan to prevent breaking the flues should not touch each other.

A clear light is not only pleasant to look at, but is better for the eyes than a dull flickering one, and it is impossible to have clear lights unless the flues and burners are kept clean and bright. Wash the flues every morning if the lamp has been used the night before, and wipe dry with a soft cloth that will leave no lint. Keep them full of oil. An excellent method of cleaning the burners is to dissolve some strong detergent in a quart of water. Boil the burners in this ten minutes, after which wipe them with a cloth, and they will look like new. This should be done at least once a month, and if you begin when the burners are new, they will not tarnish nad turn black, as many do after using them a while. This treatment will keep the small tubes on each side of the wick clear of the gummy substance that collects in them, improving the light and lessening the danger of explosion.

A lamp shade is a great convenience when one is reading at night, and it saves the eyes wonderfully. Crepe paper makes pretty shades and is inexpensive.

SOME WAYS OF WOMEN.

If the house catches fire a woman wants to save her old love letters and the baby's first pair of shoes.

A woman goes to an afternoon tea in the same state of excitement as a man does to a horse race.

If you try to whisper to a girl she acts as if she were afraid she might try to kiss you against her will.

Most men are willing to let their wives train the children, but they insist on training the dogs themselves. This last position is very reasonable. No man ever knew anything about babies, but the dog is a kind of fellow creature to him.

Love is not getting, but giving; not a wild dream of pleasure and a madness of desire—oh, no, love it not that—it is goodness and honor and peace and pure living—yes, love is that; and it is the best thing in the world and the thing that lives longest.—Van Dyke.

Cookery Recipes

Halibut Cutlets.—Grate some stale bread, crust and all, and allow it to become thoroughly moistened in boiling milk; press the milk from it and add a cupful of minced halibut (uncooked); then add half a cupful of butter, three eggs, half a teaspoon of anchovy sauce, and a teaspoon of lemon juice. Mix thoroughly, make into cutlet forms and fry very brown in hot lard.

* * *

Soup Maigre—Cut into dice and fry in two tablespoons of butter, one carrot, one white potato, a stalk of celery, one parsnip and a large Bermuda onion; when nicely browned add a tablespoon of minced parsley and two quarts of water; cover closely and simmer slowly for two hours; season with a scanty teaspoon of salt, a saltspoon of paprika and half a cup of tomato catsup, allowing it to boil for five minutes after the last ingredients are added; strain and serve in boullion cups with toasted saltines.

* * *

Baked Bananas—Cut in half lengthwise. Put in baking dish, sprinkle over some granulated sugar and bake a chestnut brown. A little lemon or orange juice may be poured over if desired.

* * *

Cheese Toast.—Mince cheese finely, season with mustard, cayenne pepper and salt. Spread on buttered bread and set in hot oven to brown. Serve at once.

* * *

Potato Fillets.—Select long potatoes, pare and cut in fillets one-fourth of an inch square and drop into ice water. Then partially cook in boiling drippings. Remove and strain. Bring the drippings to boiling point again, drop in the fillets and cook until done. Dust with pepper anl salt.

* * *

Rhubarb is the spring fruit par excellence in the majority of households, and yet it is really a vegetable. For most people it proves exceedingly wholesome. In preparing rhubarb for the table do not peel unless the stalks are old, tough and rough. The tender pink skin cooks as readily as the flesh and gives, besides, the pretty color that tempts the eye. Never cook in tin nor in granite, unless of an excellent quality. Earthenware or the porcelain lined saucepans are best. Use little or no water in its cooking, as the juice of the plant makes sufficient syrup. In stewing, cut in inch pieces, allow two cups of sugar to one pound of rhubarb, arrange in layers in an earthen pipkin or porcelain lined double boiler, and cook without stirring in the oven or on the stove until the sugar is dissolved and the fruit tender. Cooked in this way the fruit pieces will keep whole and distinct in the clear, pink syrup.

NAMES OF TEXTILES.

The names of fabrics are in many cases derived from the place where they were first manufactured; in others, the name is bestowed in honor of the place where it first became known to commerce, or from the materials composing its texture. Thus the name muslin is derived from Mosul, in Asia.

Cambric comes from Cambai; gauze from Gaza; baize from Bajac; dimity from Damietta, and jeans from Jean.

The name damask is an abbreviation of Damasacus; satin is a corruption of Zaytown, in China.

Velvet is the Italian "vellute," woolly, and is traceable further back to the Latin vellus, a hide or pelt.

Serge comes from Xerges, the Spanish for a certain sore of blanket.

Bandana is derived from an Indian word signifying to tie or bind.

Alpaca is the name of a species of llama from whose wool the genuine fabric is woven.

Calico is named for Calicut, a town in India, where it was first printed.

USES FOR LEMONS.

Two or three slices of lemon in a cup of strong tea will cure a nervous headache.

Lemon juice (outward application) will allay the irritation caused by the bites of insects.

A teaspoonful of lemon juice in a small cup of black coffee will relieve bilious headache.

A dash of lemon in plain water is an excelent tooth wash. It not only removes tartar, but sweetens the breath.

Lemon juice is better than any drug or complexion powder for giving permanent clearness and beauty to the skin.

The juice of a lemon taken in hot water on awakening in the morning is an excellent liver corrective, and for stout women is better than any anti-fat medicine ever invented.

"Your winter flnannels don't you doff
Until it's nearly June,
For lots of folks are taken off
Bytaking off too soon."

ROCKWOOD IN CHARGE.

The Imperial Development Co., which is the parent corporation of the immense Imperial irrigation systems, has, since the transfer of the principal holdings from former President Heber to the Southern Pacific Co., taken most decided steps for great improvements of this great system within the next few years. Rockwood has been made assistant general manager, with offices at Calexico. This year the embarrassment has not been in the shortage of water, but in the large quantity which could not be controlled, and has kept the canal full at all times. Probably one of the first extensive improvements which will be entered upon will be the construction of new head gates at the Colorado river, which will aid in controlling the supply.

Regarding some of the matters to be settled by the new management, the Imperial Press speaks as follows:

It is the purpose of the new management to take up and settle every one of the matters that have been in controversy between the Imperial Water Companies and Imperial valley settlers, and the California Development Company. This will doubtless include a new deal in Water Company No. 8, a settlement for damages for crop failure on account of water shortages, and just treatment for Water Company No. 5. In the hands of the master minds now guiding the course of the California Development Company it can be confidently predicted that all these matters will be soon adjusted and a spirit of fraternal co-operation pervade the forces now united for the upbuilding of our beloved Imperial Valley.

SMALL FARMS MADE TO PAY.

In Denmark there are 224,000 rural landowners. More than half have not more than one acre, 96,000 have less than four acres, and only 2,000 have more. The small landowners mainly occupy themselves wtih the egg and fowl industry.—Northwest Horticulturist.

To prevent milk from curdling in oyster soup, first boil the oyster liquor and skim thoroughly, then add the milk to it with the desired thickness, butter and flour rubbed together. Watch it carefully, and the moment it bubbles add the oysters, stirring constantly and carefully with a wooden spoon, until the scalding point is again reached. Take it from the fire and add the seasoning.

Some housekeepers always make a point of buying their soap in large quantities, as they say it improves with age.

It is not generally known that ordinary pulverized charcoal is an excellent preventive of typhoid and yellow fever. Stir plenty of the charcoal into a cup of syrup, and take a teaspoonful three times daily. After each dose take a pinch of salt. This is an excellent medicine to ward off the dread disease, simple, yet effective, and used by an eminent physician when visiting his fever patients.

In making good butter there is always plenty of time to do everytaing just right; if you find there is not time, then you are not making good butter.

Dairying is a question of feed as well as of breed.

Los Angeles Markets.

Los Angeles, July 13, 1905.

Butter.

Butter still stands at last week's quotations with a very firm feeling prevailing. The shipments have materially fallen off, even those from the upper Coast counties being much lighter than before. Receipts are now about two-thirds what they were thirty days ago.

B. of T. Creamery 50
Valley Creamery, fancy 50
Coast Creamery 45
Fancy Dairy 45
Cooking, per lb .....17@18

Cheese.

Cheese has been more plentiful, lowering from one-half to three-quarters of a cent. This is especially true of Anchor brands and some sellers have claimed that the reduction was in order to keep out shipments of outside stuff. A carload of fancy Wisconsin was received on Tuesday and at once placed in storage.

Eastern, firsts .....18 @19
Eastern, seconds .....16 @17

POULTRY.

POULTRY—Old Roosters, per doz., $4@5; young Roosters, $6.50@7.50; Fryers, $4.50@5; Broilers, $2.25@3.50; Hens, small, $4.50@5; large, $5.50@6.50; Live Turkeys, per lb, 18@21c; Spring Turkeys, 24@28c; Ducks, old, $4@4.50; young, $4@4.50; Geese, per pair, $1.50@1.75; Goslings, $1.50@1.75; Pigeons, per doz, old, $1.25@1.50; young Pigeons, $1.50@1.75.

FRESH FRUITS.

Apples, per box, fancy, $1@1.50; common to choice, 50@75c.

Apricots—Per box or crate, 25@65c; bulk, per ton, $10@25.

Figs—Per large box, 75c@$1.50; small box, 50@75c.

Pears—Per box, Bartlett, No. 1, $1.50@1.75; common, 75c@$1; other varieties, 50c@$1.25.

Peaches—Per box, 40@75c; carriers 90c@$1; basket, 40@65c; large boxes, 85c@$1.25.

Plums and Prunes—Per small box, or crate, 40@75c; as to variety; large boxes, $1@1.50.

Nectaries—Per crate, White, 50c; Red, 75c@90c.

Grapes—Per crate, Seedless, 75c@$1.25; Black, 75c@$1.

Cantaloupes—Per crate, $1.25@$2.25; Watermelons, per lb, 1½@2c; per doz, $1.50@3; Nutmeg Melons, $1@$1.50.

Blackberries—Per chest, $2.50@4.

Currants—Per chest, $4@5.50.

Loganberries—Per chest, $3@5.

Strawberries—Per chest: Longworths, $2.50@5; large varities, $2.50@3.50; Santa Clara berries, $2.50@4.

Huckleberries—Per lb., 12½c.

VEGETABLES.

VEGETABLES—Asparagus, per lb, 3@4c; Tomatoes, small box or crate, $1@1.25; large box, $1.75@2.25; Green Peppers, per box, $1.50@2; Dried Peppers, Southern, per lb., 10@12½c; Stockton, 11@12c; Okra, per lb, 12½@15c; Beans, per lb, Green, 1@2c; do, Wax, 1@2c; Green Peas, per sk, $1@1.50; Cucumbers, per box, $1@1.35; Summer Squash, per box, 25@50c; Egg Plant, per box, $1.50@2; Garlic, per lb., 2½@3½c; Green Corn, per sk, 50c@$1; per crate, $1@1.50.

POTATOES—Per ctl: River Burbanks, in boxes, 90c@$1.25; in sks, 50@85c; Early Rose, 50@75c; Garnet Chile, 50@75c.

ONIONS—Per sk: New Red, 40@75c; Yellow, $1.25@1.35.

DRIED FRUITS.

Quotations on dried fruits are almost impossible to secure. In futures on prunes the growers are still strong in their demand for three cent basis, some even holding for three and a half. Apricots are quoted at seven and a quarter and seven and a half for extra fancy stock, with some quotations for indifferent goods running as low as five and a quarter.

HONEY AND BEESWAX.

HONEY—New crop, Comb, per lb, 10@11c; Extracted Water White, 6@6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

HOPS.

The price of desirable stock is nominal at 24@27½c per lb, according to quality, many producers demanding thirty cents.

LIVE STOCK.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@5½c; rough heavy, 4¼@4½c; common, 3½@4c.

HAY AND FEEDSTUFFS.

HAY—Per ton: Wheat, $10@14; Wheat and Oat, $9@13; Oat, $8@12; Barley, $7@10; Clover, $7@10; Alfalfa, $7@10; Stock, $5.50@7.50. New crop Wheat, $9@13.50; Oat, $5.50@11, Wheat and Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice Grades per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

GROUND BARLEY—Per ton, $22.50@23.50.

MIDDLINGS—Per ton, $25.50@28.50.

FLOUR AND CEREALS.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 shipping, per ctl., $1.50@1.55; White Milling, good to choice, $1.57½@1.65.

OATS—Good to choice, White, nominal; Red, $1.22½@1.30 for new crop.

BARLEY—Choice No. 1 Feed, $1@1.05; off grades, 96¼@98¾c; Shipping and Brewing, nominal.

CORN—Good to choice, per ctl., California, new, large Yellow, $1.40@1.45; small do, $1.47½@1.50; White, $1.37½@1.40; Eastern, Yellow, $1.37½@1.40; White, $1.37½@1.40; mixed, $1.35@1.37½.

RYE—New, $1.40@1.47½.

CITRUS MARKETS

NEW YORK.

Total shipments during last week were still further reduced, showing an aggregate of 60 cars at auction in New York market as against 71 for the week prior and 65 for the week preceding that. Supply was slightly more than the midsummer season, with its large supply of deciduous fruits could carry to the best advantage, and there was a slight decline on sound fruit, while much of that with heavy decay brought practically nothing. Navels practically out of the market. Valencias commanding the principal attention. The few navels which are in market at the present time are the cold storage supplies, handled in a local way only.

About 50,000 boxes of imported lemons were offered during the week. The hot weather increased the demand for these so that sharp advances were maintained. Californias also advanced under this stimulus until $3 to $3.60 were readily obtained for the more desired sizes.

At Monday's auction 16 cars were sold. The bidding was rather brisk, the hot weather proving a stimulus to the entire market. The serious drawback of fruit in bad condition was a bad handicap. Bidders took little fruit as possible, working from hand to mouth basis. Valencias were the favorites, some fancy fruit even commanding very high prices. Lemons were firm, tending upwards.

Some quotations were: Valencias: Coyote, ch, O-C Ex, $2.65; Royal Knight, xf, S B Co Ex, $3.50; Bear, xf, O-C Ex, $3.85; Oak Knoll, Oak Knoll Park, $2.85; Florencia, fy, J M Riley, $3.45; Rose, xf, Redl., O G Assn, $3.50; Tiger Head, xc, I L Lyons, $3.15; Rialto Girls, fy, F P Corson, $3.35; Old Mission, ch, C C Chapman, $4.10; Azusa Girl, fy, A P Nelson, $3.95.

Navels commanded $1.50 and up; Sweets, $1.25 to $2.60; Mikes, $1.25 to $3.70; Lemons, $3.85 to $4.75.

Tuesday's market showed a slight weakening under a continued receipt of poor fruit, also a slightly decreasing demand. Navels were practically unfit for use. Valencias were fine. Total sales aggregated ten cars. Lemons were exceedingly high, nothing of fancy grade being obtainable for less than $5 per box.

Some quotations were: Valencias: Tunnel, ch, S-T Ex, $2.85; Red Shield, xc, A C G Ex, $3.55; Golden Eagle, st, C C Chapman, $3.35; Eagle Head, xf, I. L. Lyons, $3.55; Rose, xf, Redlands, O G A, $3.85.

Mikes, $2.60 to $3.60; Seedlings, $1.75 to $2; Bloods, $1.65 to $1.90; Sweets, $1.90 to $2.50.

BOSTON.

Monday's auction took five cars. Valencias commanded ready sale at good prices.

Some quotations were: Valencias: Vista Bonita, fy, W F Whittier, $4.40; Crocus, xf, West Hgh., $4.25; Quail, xc O-C Ex, $3.85; Perfection, fy, CCU, Redlands, $3.65.

Sweets, $2.15 to $2.60; Mikes, $2.85.

Tuesday's auctiin took only six cars. Valencias ranged from $4 to $5; Mikes $2 to $2.50; Sweets, $1.35 to $2.95; Lemons, $3.30 to $4.20.

PHILADELPHIA.

Seven cars sold at Monday's auction. Lemons were fairly sound, selling from $3.30 to above $5.

Some quotations were: Valencias: Mocker, or, Spence Ft Co, $4.05; Blue Globe, xf, Riv Ex., $2.50; California Orange, st. Riv Ex, $2.75.

PITTSBURG.

Seven cars sodl at Monday's auction, Valencias commanding $3.15, $3.60 and $4. Mikes sold at from $2.50 to $3.60 and lemons at $3.75 to $4.50.

NEW YORK.

Fourteen cars sold at auction Wednesday. Weather intensely hot. Business almost at standstill. Sound fruit found ready sale at only fair prices.

Lemons booming as high as $6.50 secured for some boxes. Some jobbers are asking $7.50.

Some quotations are: Valencias: Rose, xf, R O G Assn, $4.15; Blue Mtn., fy, Riv Ex., $3.90; Rialto Girl, fy, Corson, $3.65; Eagle Head, xf, Lyons, $3.40.

Sweets, $1.85 to $3; Mikes, $1.10 to $2.40; Seeds $1 to $1.75.

Lemons, $4 to $6.

BOSTON.

On Wednesday seven cars offered; three withdrawn.

Valencias, $3.70 to $5; Lemons, $3.50 to $5.50.

PHILADELPHIA.

Eight cars Wednesday.

Valencias, $1.30 to $5; Lemons, $4.50 to $5.50.

CITRUS SHIPMENTS.

Total citrus shipments since Nov. 1, 27,439, of which 3137 were Lemons.

The best dairy cow is the one that produces the greatest amount of butter fat at the least cost. No cow can do this unless she has been bred for it or unless she be a freak, and that sort of a freak is not very common.

Extensive field fires in Evergreen valley and the timbered hills back of Las Animas valley, near San Jose, last week caused immense damage by burning over thousands of acres of hay, grain and pasture lands.

The weather and crop conditions for the week ending July 10 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—The weather was clear during the week, with light fogs in the coast districts towards the close. High temperatures prevailed throughout the State nearly all the week, and in many places previous records were broken on the 7th and 8th. Maximum temperatures were reported as follows: San Francisco, 98 degrees; Sacramento, 110; Red Bluff, 114; San Luis Obispo, 104; Fresno. 115; Cloverdale, 115; Santa Rosa, 109; Palermo, 116; Porterville, 114; Riverside, 103; Los Angeles and San Diego, 86.

Harvesting and threshing are progressing rapidly and hay baling continues. The grain crop is somewhat disappointing and is much below early expectations except in a few places. In Southern California the yield of wheat and barley is the best for several years. The hay crop is above average in nearly all sections. Sugar beet harvest continues; the yield is reported above average. Beans were not seriously injured by the heat and give promise of a large yield. Hops, corn nad potatoes were benefited by the warm weather and are making rapid growth. In some sections the yield of hops will be fully average.

Deciduous fruits and grapes were probably injured to some extent by the extreme heat but reports thus far do not give any reliable estimates. Fruit picking, canning and drying are in progress and large shipments were made during the week. Grapes are in market in limited quantities. Lemon shipments from San Diego were unusually heavy. Oranges are in good condition.

Eureka Summary.—Continued warm and dry in the interior. Oat hay cut and in shock; crop heavy, but considerable rust. Pears, peaches and small fruits are light and potatoes poor.

Los Angeles Summary.—The warm weather benefited citrus fruits. Lemon shipments are brisk. Irrigation water is plentiful. Gardens and orchards are in good condition. Hay harvest is about over and baling is in progress. Apricots are a fair crop; drying has commenced.

There are no reports of damage by the heat and it was probably beneficial to deciduous fruits, grapes and walnuts. The grain crop is being rapidly harvested and threshed, and it is the best for many years; shipments will commence soon. Sugar beet harvesting is progressing. Beans were not seriously damaged by the heat and prospects are good for a large crop.

IN WOMAN'S BREAST
ANY LUMP IS CANCER
Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.
THREE PHYSICIANS OFFER $1000
If They Fail to Cure Any Cancer
Without KNIFE or PAIN AT HALF PRICE for 30 days. Not a dollar need be paid until cured. Only infallible cure ever discovered. ABSOLUTE GUARANTEE.

... COULSON'S SPECIAL MOULTING FEED ...

A FEATHER GROWING FEED

A specally prepared or properly balanced mixed feed containing the right component parts of materials for producing the rapid growth of feathers.

The term "molting" denotes the process of the birds shedding their old feathers and growing new plumage.

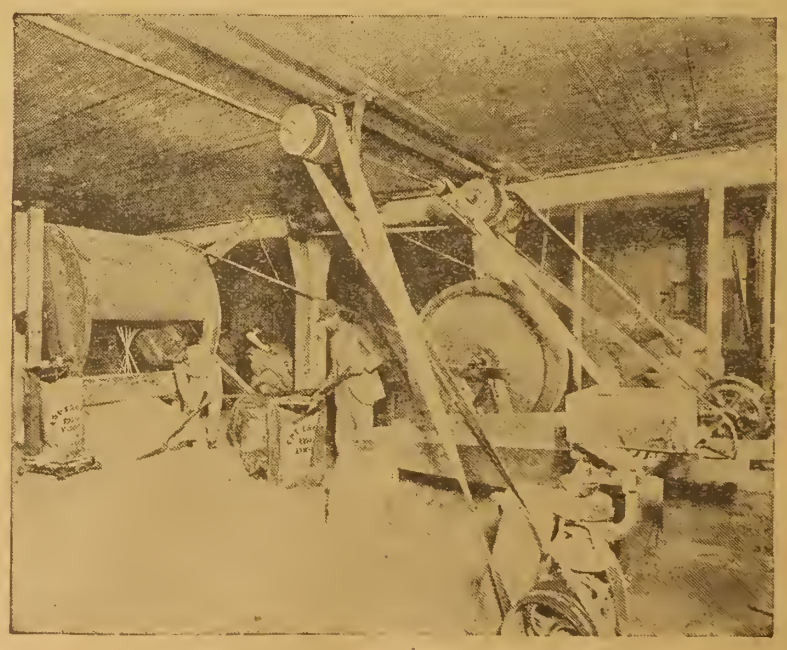
It is not necessary to starve the hens to make them molt, neither is it necessary to stop egg production. Hens fed with good feed and with good digestive capacity, can lay eggs and make feathers at the same time.

Keep hens for profit—intelligent feeding returns a profit. Feed a good balanced ration (Coulson's Egg Food) the year round so as to keep the fowls in good normal and healthy condition; then when the molting season comes and you want your fowls to molt, and get through molting before winter sets in, just start feeding them COULSON'S SPECIAL MOLTING FEED, and the fowls wil soon be getting a beautiful glossy plumage (due to articles in the feed) and will get their new feathers in short order; for in this Special Molting Feed they get the material needed for feather production.

Knowledge is power, and the knowledge needed now by poultrymen is to know just what foods contain the most of certain kinds of nutriments, and will produce the rapid growth of feathers and also keep the bodily health of the fowls. This is why it pays to feed Coulson's Special Molting Feed during the molting season.

Young healthy fowls fed on the right kind of feed will complete their molt in sixty days; older fowls will take longer. Birds not properly fed during the year will be weak during the molting season; they lack vitality, and will molt very slow. probably taking six or more months to get their new growth of plumage, and quite a number of the weaker birds die from the strain of molting or from exposure.

Loading Cars with Coulson's Food for Laying Hens



Interior Scene of Coulson Co. Manufactory

Young birds will molt and grow new plumage at the expense of health; old fowls will keep up their bodily needs, and go bare unless they are furnished the proper food to make the feathers grow.

The molt is a strain on the vitality of any fowl, for besides keeping up the heat and wear and tear of the body, the fowl must produce and grow new feathers; consequently the fowls should be fed a good rich food containing the right compoment parts of ingredients that will make feathers, and unless fowls are kept in good healthy condition, and fed the right food, many fowls will die during the molting season.

When fowls have been fed the year around one meal a day of Coulson's Egg Food so that they are in fine health at the beginning of the molt, if they are fed then for two months on Coulson's Special Molting Food, the growth of new plumage will be rapid, the new feathers appearing gradually, as the old feathers drop off; and the bird may never appear worse than a little rough coated, and the egg production will average about one in three days. Some birds even doing better according to their digestive capacity.

Any one keeping fowls will surely be pleased to get eggs in fall and winter when eggs are bringing the highest prices. For this reason one should assist the fowls during the molting season by feeding them Coulson's Special Molting Feed, so that the fowls will get through the molt before the winter weather sets in. The fancier also desires his fowls to complete their molt early so they will be in exhibiting condition for the poultry shows.

Fowls fed on Coulson's Special Molting Feed will have a beautiful bright glossy plumage (a condition of perfect health), and will be pleasing to the eye, so that the owners will be proud of their birds. This feed supplies the fowls with the minerals and protein substance, etc., needed for the growth, so that fowls can complete their molt and begin laying before winter.

Advantages of Ensilage as a Dairy Feed

It is the Cheapest and Best Fodder Used in the Industty Today

The increasing use of the silo, even in California, where it is claimed by proper following of green crops and use of damp land pasture the year around, we may have succulent food for milk cows at all seasons, is notable. This is not without reason, for low cost of such food and its value as a milk producer has been proved so conclusively that its increasing use will probably be continued until some better form of food is devised. The claim formerly made that it tainted the flavor of milk has been disproved for today almost every dairyman who has used it will assert that there is no possibility of taint of any ensilage being taken to the milk from the cow's body though it often is the cause of tainted milk where its odors have been allowed to come in contact with the fresh drawn milk. Of course, it goes without saying, that there have been many failures and many have condemned the method of stock feeding but the longer experience with it and discovery of past mistakes is fast wiping out the prejudices. Silos so built as to admit air, either by faulty construction or by being so slightly built that they give way under the great pressure after filling is the cause of many failures. For instance, the old fashioned, square-built silo is more liable to spring out under the pressure, thus admitting the air and the moment air is admitted to the sides of the packed feed it begins to decay. Cases are cited where fifty to one hundred tons of ensilage have been destroyed by this mistake. Silos now are almost invariably built round and either of staves or of studding and so built as to be strong enough to hold the great pressure brought upon it by the packed feed. This pressure, in fact, is much greater than usually supposed. For example, a silo filled with cut corn to a depth of ten feet has an outward pressure of one hundred and ten pounds per square foot; of three hundred and thirty pounds at thirty feet and the enormous pressure of four hundred and forty pounds per square foot at a depth of forty feet. Or, in other words, every foot in depth gives an added outward pressure of eleven pounds.

But regarding the construction and some valuable points as to silos, we give below quotation from an address given last year by Mrs. Minna E. Sherman, of Minnewawa Ranch, Fresno, before several of the Farmers' Institutes. The address was given on the programs as "The Silo and Soiling Crops." We take this week, however, only the first half of the address, that which pertains more particularly to the silo, its advantages and construction. Next week we will refer more to the crops used for ensilage and to manner of putting up.

* * *

"The finest dairy cow has no powers by which she can produce more milk than is furnished by the digestible elements of her rations; therefore, while she must have plenty to eat, we think it can be furnished in its best form and at less cost, by making ensilage from the crops grown on the farm.

While the importance of decreasing the cost of feeding may not seem to the individual dairyman very great—providing his cows are already paying expenses, yet, when we consider the dairy industry represents the investment of more money and of more energy than all the fruit grown in the United States, to lessen the cost of feeding of the cows becomes one of the leading questions of the dairy world.

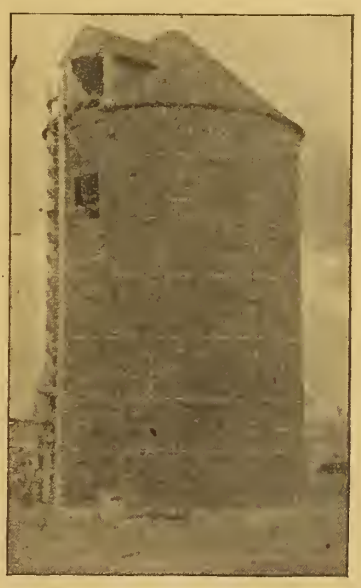
The name of the inventor or the discoverer of the art of making ensilage has long been lost. Perhaps, like the wheelbarrow, ensilage came into existence in the past because the world's economy had a great necessity to be filled.

Every year the value of ensilage as a food increases in our opinion. The waste of the green feed in filling a silo, and again in feeding it out, is much less than the loss from handling brittle hay. We have often wished for a simple way to estimate how far the loss in handling alfalfa hay would go toward paying for the extra hauling of it when put into the silo green. The silo is cheaper than a hay mow, for when it is considered that a silo of three hundred and fifty tons capacity for ensilage, will hold only thirty-one to thirty-two tons of hay, we can see the saving in building space; or if a good barn has been already built, the silos may be placed inside and the expense of a second roof saved.

The two silos on Minnewawa ranch were built before the cheaper form of stave silo had been used long enough to demonstrate their merits. For they are good and they are cheap—so cheap that no one should hesitate to put one up for even a few cows, any more than they should hesitate to buy a small separator. To our minds, both are a necessity in even the ten cow dairy.

The two silos seem to be practically indestructible—excepting by fire—so we are not likely to build another silo; yet if occasion demanded a third one, it would be built in the cheaper stave form.

The two silos are of wood, built entirely above ground; a low brick and cement foundation wall raises the wooden sides 18 inches above the ground. The interior ground surface is filled with six or eight inches of coarse creek sand placed directly upon the natural surface of the ground. By raising the interior surface, good drainage is secured. If it were not raised, the weight of the ensilage would depress it below the outside surface, and the rain water as well as the extra water from the silage would be held and rot both the ensilage and the building.



A Round Silo.

This plan is practicable for the reason that we are free from rats. Where they abound, a cement floor with a good, sloping drain must be used to keep them out, or they will burrow into the ensilage, leaving long tracks of mouldy feed where they have admitted the air from the outside.

The first silo we built is square, or rather, has two square pits in one building. It is 32x16 feet, and 24 feet high from the sills to the roof-plate. It is divided into two pits, each 16 feet by 16 feet. The framework is formed by standing studdings of common mountain pine on end every fourteen inches. On the inside the corners are braced and the angle reduced by placing three-foot pieces across them, while the outside form is left square. Inside the rough sheeting boards are placed horizontally close together over the sides; then heavy tarred paper is put on and carefully lapped to exclude all air; over this is placed the surfaced and matched four-inch lining boards. Outside the sheathing is covered with rustic and painted—for there is pride taken in the appearance of the farm buildings around Fresno. It also seems to me no one can afford to have unpainted buildings for the dirt to lodge on, for if the owner permits dirt on the outside it is hard to convince the men inside the building that "Cleanliness is next to Godliness."

One of the corners of each pit is fitted up as a chute with doors opening inward, one after the other, all the way down the side. These doors are closed as the silo is filled, and tarred paper placed over them, then sacks nailed closely on, and a second rough door holds them pressed in firmly. These doors must be as close as the body of the silo itself, or the air will enter.

On the roof of the silo is a dormer window, into which the end of the elevator carries the feed, cut into two inch lengths by the cutter. The cutter stands on a platform raised four feet from the ground and is power-driven. The wagons unload either onto the platform or directly on the traveling table of the cutter.

The large silo is 30 feet highand 26 feet in diameter. It is circular and stands on a brick foundation. It is built the same as the other, except there are no corners to cut off and consequently no inside feed chute. So in removing the silage, we send it down outside, using a long canvas sewed into a cylinder, or sack, with an iron hoop in each end to keep it spread, one resting on the wagon bed, the other at the door nearest the level of the silage. This makes the loading of the wagon easy and no ensilage is wasted. In the East, some of the dairymen are of the opinion that it does not pay to tar the inside of the silo, but let the acids from the ensilage eat the lining boards and destroy them in four or five years. Now we think it pays to tar every year. After seeing this opinion in print, we watched to see just how much labor it was to tar the inside. The two 16-foot square pits of the small silo took 4½ gallons of tar and 10 gallons of gasoline. Texas Sam and Missouri Joe were three and one-half hours putting it on. The lining boards in the silo are as good as when first

(Continued on Page 66)

STAND TOGETHER.

The loss to produecrs by scheming and by manipulation of markets by middlemen is most exasperating to the grower and is more general in California, we believe, than with the Eastern producer, because of greater dependence from the great distance from market. The only known remedy and one which has proved out is for the growers to stand together—to co-operate. On this point an address sent to the growers of raisins by the California Raisin Growers' Co. has this point:

"Can the grower who has toiled and sweated during the past eight months, plowing, pruning, cultivating, irrigating and taking chances against frosts, worms, spiders and mildew, view with complacency the spectacle of the middle man selling his produce four months before it is ready for market without even the scant courtesy of consulting the producer in order to learn whether or not he has some slight opinion as to what price the product should be offered to the trade. One year of intelligent combined action on the part of the growers will teach the short-seller a lesson, of which he is badly in need. Last year the packers performed the same trick (successfully too) to the great loss of the growers.

About one thousand cars of seeded raisins were sold early last season before any quantity, practically speaking, was contracted for from the producer. This was another flagrant case of shorting the market to the detriment of the interests of the grower. Why? Because the short selling last season by the packers was the direct cause of those packers agreeing among themselves to pay the grower no more than $35 per ton in the sweat-box. The grower was caught unorganized for the first time in seven years, and forced to submit and deliver his raisins at a starvation price. The interests of the producers are of no concern to the middle man. As a rule, he has no more sentiment in his general makeup than a hard-boiled egg, and considers it only business to depress the market as low as possible at the time growers are compelled to sell, and if to accomplish this result it be necessary for the packers to combine there is no difficulty in effecting such combination. This fact is illustrated by the local situation today concerning dried apricots. Under ordinary competitive conditions, the buyers of dried apricots would have been swarming in the fields weeks ago to secure this line of fruit. The quality of dried fruit on the coast carried over from last season, other than a few prunes, practically amounts to nothing; and the present conditions of supply and demand are all in favor of the producer. At the same time, the actual apathy shown by the dried fruit handlers in the San Joaquin valley in the matter of buying dried apricots indicates nothing more nor less than that another "dried fruit combine" has been formed up in the salty air of San Francisco for the purpose of again inaugurating the "relieving process" now to be applied to the apricot grower.

The thirty-five dollar per ton in the sweat-box of last season for raisins worked so beautifully that it is a valuable object lesson to the packer; and from his point of view, why not apply the system to dried apricots and later on to dried peaches?

So brazen has the situation become that as early as a week ago a large number of apricot growers in Kings county met and as a matter of self-defense agreed to pool their apricots and demand a price justified by present eastern market conditions. The fact that apricot growers find themselves compelled to adopt such action is significant and proves that anything the grower produces is meat for the packer, and by the packer for his own benefit should be "systematized."

Then why under the sun can't the grower "systematize" just a bit for himself?

The only answer we hear is a discouraged "Why?"

UNITED PACKERS AND GROWERS.

The California Raisin Growers Co. has issued a call for a meeting of the stockholders in that company at Fresno today, at ten o'clock. The meeting has been called by the board of directors for the purpose of submitting to the growers a proposition to unite with the packers in forming a packing corporation upon a permanent basis.

The directors of the company have held an extended conference with the packers with the result that this conference of all the growers is called. Should a combination be effected, it is to be hoped that it will lead to the greatest good to the greatest number of growers.

The details of the plan of amalgamation have not yet been worked out, but there is no question that both sides, that is, the directors and the packers, are favorable to the general idea of combination, provided the details can be worked out equitably and satisfactorily.

Regarding the advisability of this move, the Tulare Register says: The chief advantage claimed for the plan is peace. It will unite what have been antagonistic elements of the business and make their interests common. Packing will be done at cost and dividends will be equally divided among grower and packer. It will save duplication of packing plants and constant warfare. It will put the growers into possession at once of the avenues of trade. In fact, its advocates can cite every business reason for it; how it will appeal to the growers remains for the mass meeting to determine.

Bone dust and wood ashes are the best fertilizers for strawberries and supply all that may be lacking in almost any soil for their growth.

Keep the ground which the crops occupy free from weeds and soft and mellow.

BENEFICIAL PARASITES IN SONOMA COUNTY.

In the report made by the Sonoma County Horticultural Commission, of which Mr. Bremner is secretary, we note that the brown apricot scale has found its finish, or at least is being controlled by the little parasitic chalcid fly, Comys fusca. This apricot scale has proved a serious menace not only to apricot trees, but to many forest trees in the northern part of the State so that this beneficial fly which has been doing the work for the last few years, now gaining control of the situation, is a great boon to all parts of the State.

As to the control of the San Jose scale, the report says: "We now have one internal (Aphelinus fucipennus) and three general feeding parasites, Chilicorus givulnurus, C. similis and Rhizobius lopantha) feeding on them so that now there is no part of the country within our knowledge where these beneficial insects are not keeping down this dreaded pest.

On the olives the black scale was very abundant but by importing the egg parasite (Scutellista cyanea) and our old friend (Rhizobius ventralis) our olive trees are rapidly assuming their natural bright color and the olives will undoubtedly be free from the black smut this coming season.

As to the canker worm, we have conclusively proven that the tanglefoot which we have used for the past two years, and with which we intend to cover the remaining territory this fall, is not only the most effective remedy used, but will absolutely clean up the affected orchards when carefully applied."

In the matter of grape vines, the report says that resistant vineyards have not only proven themselves thoroughly resistant but the quality and quantity of vines have improved in the resistant stock.

THE DISCONTINUANCE OF TULARE EXPERIMENT STATION.

By recommendation of Professor Wickson, University regents have ordered the discontinuance of the experiment station at Tulare. This will reduce the number of experiment stations in the State to two; the one located at the University at Berkeley and the other at Pomona. There are two forestry stations, one at Chico and one at Santa Monica. Also a poultry experiment station at Petaluma. In this respect, the regents of the University have suffered under the embarrassment of attempting to carry a heavy expense with a small appropriation. For that fund, they received from the United States Government $15,000 and Professor Wickson, in a letter to the Chamber of Commerce at Tulare, replying to its protest against the removal, states that the maintenance of these permanent sub-stations from the Hatch fund is disapproved at Washington and is likely to involve us in trouble even to a possible withdrawal of a portion of that fund.

Also that the extension of special field investigations and experiments into problems at the points where they rise to pressing importance, is a more direct and less expensive method of reaching valuable results.

This action is to be regretted though we fully appreciate the embarrassment under which the State University labors in attempting to hold up so many stations and at the same time do thorough work. It it to be regretted because the Tulare station is in the midst of a magnificent agricultural country with cultural problems of its own which we believe the farmers there may be greatly aided in by a well conducted experiment station. The people of Tulare provided the station grounds and the funds for constructing the buildings and they urge this as one of the reasons for the continuance of the station work. A committee consisting of John Tuohy, P. J. S. Montgomery and L. H. Haney are pressing the matter of continuance of the station and hope they may accomplish that result.

SUCCESSFUL BEEKEEPING..

Many have an idea that successful handling of bees requires but little study or scientific knowledge of the calling. But we notice in an Eastern exchange on this point a few words which may be of interest to those contemplating engaging in the industry:

I have worked with bees nearly fifty years and have seen large and small apiaries started all around me. The most of them disappeared very soon. In every case of such failure I found that the man either did not read or was not able to understand the little he did read.

Now we have to consider another point. This self-education by reading and studying is the most difficult way to obtain a certain knowledge. Some degree of elementary knowledge is necessary for it, also some energy, I might say a love for science; a much easier way it is if we obtain this knowledge by and by, if we practically work in the apiary under the supervision of a well educated apiarist, who explains everything, every operation, not only practically, but in every case gives the scientific reason why something must be done in this and not in another way.

I will say again, to be a successful beekeeper the man must possess the necessary scientific knowledge, then and only then he will know every time what to do if something unexpected happens in the apiary and he will be able to improve his practical operations. The late Baron Berlepsch, one of the most prominent beekeepers of Germany in the last century, said: "At first learn theory, or you will remain a bungler in practical beekeeping all your life." Here the word theory has another meaning from that for which it is generally used in the United States. Here theory means only a hypothesis not entirely proven, in Germany the word is used for science.

BEE-ESCAPE SWARMING.

For three seasons I have used the following plan with success. When I find larvae in queen-cells so that I know the colony is preparing to swarm, I put a body filled with frames of foundation on the bottom board, next to a queen-excluding board, then the surplus cases, next a porter bee escape board; on this the body containing the frames of brood, and lastly the hive cover. Leave the hive in this condition on the old stand till the field bees have had time to pass through the bee escape, say twenty-four hours. So far the manipulation is the same for all purposes. The next thing to do is to introduce a queen into the colony below the queen excluder. This may be the old queen taken from the brood-nest above, or another. If another, the old queen may be left where she is till I decide what to do with her. If I wish for increase, at the proper time, whenever I think a sufficient number of the newly hatched bees have gone below, or I conclude I have left in the old brooder enough brood and bees for the nucleus of a new colony, I remove the old brood nest to a new stand. If I do not wish for increase I may kill the old queen and let the young bees go below through the bee escape till all are hatched, or let the old queen continue laying for a while before she is removed. If I put the old queen below and wish for increase, I introduce a new queen above and make a new colony at the proper time as before. If I make the bees above queenless, I usually keep queen cells cut out—a small job, for the larvae soon becomes too old, although I have got along all right by laying a piece of perforated zinc over the hole of the bee-escape.—Bee Gleanings.

FOOD VALUE OF HONEY.

Few people know the true value of honey as food. A great many children are daily overtaxing their delicate digestive organs and laying the foundation of an invalid life by the excessive use of sugar, candy and other delicate sweetmeats. If their parents would only give them honey instead, they would not only find it a good wholesome food, but very restful to their digestive organs, as honey is the only sweet that is practically predigested.

The honey today is just the same as it was in the olden times. It is one of nature's sweets. But let us look into the matter from a scientific point of view. The physician often recommends honey for sore throat, coughs and other troubles, and because honey is not only predigested to a great extent, but it is a very good antiseptic. The best remedy known to medical science for fumigating to kill disease germs is formaldehyde gas, because it unites with the oxygen of the air to produce formic acid, and is therefore effectual. Years ago this was not known, and the only means known then to obtain formic acid was from bees or ants, and, strange as it may seem, formic acid, the great germicide, always occurs in honey, and is one of the natural products of the honey bee; and although honey does not contain this formic acid in large enough quantities to make it a germicide, it is nevertheless, antiseptic to a considerable extent, and is therefore very valuable in preventing disease. Dr. Gandy, of Nebraska, says that honey is a sure preventive of that dread disease of the kidneys, Bright's disease.

I have found honey very valuable in curing tonsilitis by holding honey in the throat so as to keep the tonsil in contact with the honey.

Both drones and queens are harmless and never sting the person handling them.

Some one several years ago discovered that 2160 bees could be placed in a pint measure and that it takes 336 bees to weight an ounce, 5376 to the pound.

It is necessary to give prompt attention to all the duties in bee keeping. It will be a mistake to neglect even the smallest details.

FARMERS' INSTITUTES.

Wishing to know regarding the coming institutes, both in the north and south of the State, we have written Superintendent E. J. Wickson regarding the matter and learn that there are no dates announced for either end of the State at the present time.

Regarding the conducting of the institutes in Southern California during the absence of Professor Cook, Professor Wickson writes that it is the intention to carry on the southern institutes very much according to the plans in the past, with possibly somewhat different arrangements of dates.

The Italian bee is a better worker and more easily controlled than is the black variety.

Spring is conceded as the best time of the year to start in the bee business.

NATIONAL IRRIGATION ASSOCIATION.

The thirteenth annual convention of the National Irrigation Association will be held at Portland, Oregon, Aug. 21st, 22d, 23d and 24th. It is probable the attendance will be the largest in the history of the Association.

Immigrants are arriving at the rate of a million a year, but too few of them are farmers, judging from the wails from farms about scarcity and wages of farm help.

There is one postal department graft too sacred to be interviewed—its contracts with railroads.

To Destroy Wild Mustard

The Cultivator has frequently referred to the use of spray with copper sulphate for destroying wild mustard, but having request for more explicit information, we take the following from the Farmer's Tribune, as giving a more extended notice of it and more directions as to handling the spray:

In 1897 a Frenchman by the name of Bonnet discovered that a great many weeds can be killed by spraying them with certain solutions of chemicals, such as copper sulphate, iron sulphate and nitrate of soda. Shortly after the announcement of this discovery, a great deal of experimenting followed, especially in Europena countries, and the statements made by Mr. Bonnet were verified.

Since then a number of our stations have experimented with spraying different weeds with copper sulphate and found that this chemical is especially adapted for killing wild mustard. A two and a half to a three per cent solution, that is about eight or ten pounds of copper sulphate per barrel of 40 gallons of water, has been found to give the best results. This strength of solution does not injure such crops as corn, wheat, barley and oats, but it does kill mustard. The solution should be applied with a spraying outfit. A one-horse six-row potato sprayer with a tank capacity of about 100 gallons is well adapted for this work. These sprayers throw a spray about 18 feet wide and with such a sprayer a man is able to cover about 20 acres of ground per day. Consequently, the work of applying the spray will not be expensive. Copper sulphate may be purchased at drug stores at from eight to ten cents per pound in large quantities, but if a great deal of this chemical is needed, it should be purchased from wholesale dealers where it can probably be had for from five to seven cents per pound. If a three per cent solution is used it will require about 40 gallons of the solution to spray an acre. Hence, the cost of the sulphate should not exceed 75 cents per acre. The spray should be applied on a clear, bright day rather than on cloudy and damp days. It is scarcely necessary to say that the solution should be applied a couple of days before rain, otherwise it will be washed off before the mustard is killed. The earlier in the season the spray is applied, the better. That is, mustard is more easily killed before it comes into bloom than when it is in bloom.

This copper sulphate solution will not only kill wild mustard, but it will also, according to experiments at the New York station, kill wild radish, wild barley, young penny grass, shepherds-purse, wild buckwheat, lamb's quarters, ragweed, dock and dodder. As has been said before, it does not injure corn, wheat, barley, oats, peas and sugar beets, consequently when the weeds mentioned above occur among these plants in large quantities, application of copper sulphate becomes a very cheap method of eradicating these weeds. Beans, potatoes, turnips and rape, however, are injured by a three per cent solution of copper sulphate, and it would be impractical to kill mustard among these plants with this solution.

There seems to be some ground for believing that copper sulphate dissolved as recommended above may also be a very effective remedy for dodder. Since a good deal of dodder is making its appearance in the alfalfa fields, we suggest to our readers who may be troubled with this weed to spray a small patch of alfalfa as an experiment and note results. There is no other way of killing dodder that we know of except to cut the crop as close to the ground as possible, dry it and then burn both the alfalfa and the dodder. The dodder goes to seed before the alfalfa does. If this copper sulphate should prove to be effective, it would certainly prove to be a boon to the alfalfa industry. Should any of our readers try this method, we hope they will report results to us."

THE NEW NAME OF THE BUREAU OF FORESTRY.

From July 1st the Bureau of Forestry is to be officially known as the Forest Service. The change was made by Congress last winter, when it provided for the Government work in forestry during the coming year, and signalized an important advance in the scope of that work. The actual control and administration of the national forest reserves, formerly under the charge of the Land Office of the Department of the Interior, is now in the hands of the Forest Service, the only branch of the public service possessed of the scientific and technical knowledge necessary for the enlightened care and use of the forests. This means that the reserves are to be made to yield to the people of the country the largest benefits which intelligent management can get out of them. Use, not reservation from use, is the essential purpose for which they exist—but use under such conditions as shall make their benefits permanent.

The field of the Bureau of Forestry has expanded remarkably in the past few years. The first Government recognition of forestry was in 1876, when Congress made an appropriation for a skilled man to prosecute a study of forest conditions, needs, and uses, and make a report to Congress. This office was continued until the Division of Forestry was created, July 1, 1886, Then from a mere office of information the Division stepped suddenly into the field of actual operations, demonstrating by example how forestry could be made to pay, and thus furnishing the one argument needed to convert private owners from scepticism as to the practicableness of a theory to the acceptance of a proved fact. When this was accomplished a new epoch in the history of American forestry opened. Since that time no single step forward has been so important as that which the use of the new name. Forest Service, now marks. This the people of the country, and particularly the people of the West, where the reserves are, will come to realize as they grasp the fact that, scientificially and efficiently administered, the reserves will soon reach their highest efficiency as contributors to the wealth and permanent development of the regions in which they lie.

It is necessary for the farmer to thoroughly understand all the routine duties of the farm.

Cultivation in a dry time is most injurious to weeds and beneficial to crops.

RECIPROCITY CONVENTION.

A call has been issued for a National Reciprocity Convention, to be held in Chicago August 15th to 17th. The immediate cause of the call of this convention is the action of Germany in discriminating against the products of the United States in its new tariff schedule which is to come into effect next year.

As an example of the discrimination against this country, the circular calling the meeting refers to the fact that the schedule relating to dried apples, pears, peaches and apricots, on all of which there is at present a duty of 4 marks (95 cents) per 100 kilograms (220.4 pounds), and in all of which a very large and important import trade from the United States has been built up, under the new autonomous schedule will be dutiable at 10 marks ($2.38) per 100 kilograms, while imports from Italy, Roumania, Austria-Hungary, and Servia (the European countries which notably produce a surplus of these dried fruits), will come in under a uniform duty of 95 cents, an advantage of $1.43 in favor of the treaty favored product. Will the superior dried fruits of our Pacific States, with their long journey to Bremen and Hamburg, be able to stand this new competition?

Another example is that of fresh apples exported from this country to Germany last year at the rate of almost 15,000 tons free of duty, which under the new schedule will be compelled to pay $2.38 per two hundred and twenty pounds.

INEXPENSIVE POT FOR PLANTS.

Mr. A. L. Davis, a farmer near Santa Ana, recently gave a Cultivator representative a good idea for a device in which to plant young tomato, cabbage or other plants or even ornamental plants to grow until ready to put into the open ground or into regular and more substantial pots. He folds brown paper, or, a good quality of old newspaper of from six to a dozen thicknesses, and wide as may be desired for the height of the pot. The length of this folded strip to be the circumference of the pot. The ends are brought together with an inch or two inch lap and held together with two or three tacks driven through and into a strip of soft pine on the inside. This makes a cylinder of paper which is given the round shape by packing a layer of dirt in the bottom, after which the young plant is planted in this paper "pot" the same as in a tin can or in a regular flower pot. Of course, it is without bottom, so has to remain in its tray or on a bench. When ready for repotting or setting in the open ground, this paper which has held the soil in place is slipped off and the small plant is placed in its permanent receptacle. These pots have been found very convenient, simple and cheap for shipping plants, and have held together for shipping long distances. Mr. Davis has even used them more than one time and finds them still good for continued use.

The directors of the State Agricultural Society held a meeting last Saturday at Sacramento to prepare for the coming State fair. Benj. F. Rush of Suisun was elected president; Thos. Fox superintendent of the fair grounds and William Lamb was made superintendent of the new pavilion. Committees will be announced by the president at the next meeting, July 29th. General admission fee was placed at fifty cents. The president was authorized to secure a band of Indians and cowboys with Indian band from Nevada, and an exhibition something of the nature of a Wild West show will be given on Monday, September 4th. The stock parade will be held on Wednesday the 6th, and the premium parade will be given on the following day.

E. T. Allen was appointed State Forester last week by the Governor. This is a new State office which carries a salary of $2400. Mr. Allen will act as secretary of the Board of Forestry, and has the employment of two assistant foresters. He is to co-operate with counties, cities, towns and individuals in promoting enforcement of the laws for forest preservation and in planning to that end. The new officer is to compile and publish the laws of forestry and distribute abstracts of them to all fire wardens. Mr. Allen will divide the State into fire districts and any county or combination of four counties may be made a fire district.

CITRUS FRUITS

By C. A. Day. Pasadena

SCUTELLISTA CYANEA.

During the spring and early summer there was very much that was discouraging in the work of the scutellista on the black scale, but with the advance of the season, conditions are improving. In the early spring except in a few orchards, but few of the parasites were found at work and in some instances, none at all. In many orchards and in the pepper trees the black scale have hatched early and ahead of the scutellista and the trees are pretty well stocked with young scale, that unless thoroughly treated will go over until next year.

The parasites are now found working everywhere, although in some cases in limited numbers. The scutellista will increase rapidly from now on until the end of the season, and by the last of August and the first of September, undoubtedly all of the old scale remaining will be parasitized. The destruction of the late scale will make it possible by thorough treatment to destroy all the young scale now hatched or that will hatch later. Under such conditions, where the red spider does not put in an appearance, which will necessitate spraying, fumigation, in connection with the scutellista, may make a thorough clean up.

The question is frequently asked, what becomes of the scutellista during the winter, and why did they not show up in greater numbers this spring? I believe this to be due to the wet winter, with an almost complete absence of scale during the winter that were in condition for the scutellista to work on, with the probability that the long period of hibernation resulted in the death of most of the old flies—bred last fall. The reason for this belief is based on the fact that in the case of citrus nurseries where there was a limited amount of scale in condition, we had a stock of scutellista in early spring and in a few orchards where like conditions of scale existed, we had the same results. In those orchards where the fly was well established and working last year, we find even now but a limited number of the parasites, and of course a reduced number of scale remaining. In other orchards where the scale was perhaps hatching through the winter and in which the parasite was first put last year, there is now from one-third to two-thirds of the scale, now in condition, that is parasitized. We know that the scutellista worked last fall and during early winter, destroying a great many of the scale then in condition. With the coming of the winter rains the scale remained stationary and did not develop into the egg stage until spring, in fact, in most of the orchards coming under my observation, there was an absence of young scale and at the present time these orchards show no half grown scale.

On Marengo avenue, of Pasadena, with its old pepper trees, was placed the first colonies of scutellista located in this section, that was three years ago the coming September. At the present time there is a good stock of old scale on these trees and but a comparatively few scutellista. Last year the mites, the secondary parasite, which attacks the scutellista, destroyed the scutellista in large numbers, allowing the scale to restock the pepper trees. So far this season only an occasional mite is found attacking the scutellista. Last year the mite was at its worst in the last of August and during September. At the latter date, in that locality, the mite destroyed nearly every larva and pupa of the scutellista under the shell of the scale. One point is true in orchard work of last year, and on most of the pepper trees, the stock of scutellista, where well established, has reduced the number of the scale, and in several instances, the pepper trees are clean. We cannot give the whole credit to the scutellista for the destruction of the scale. I know there was a stock of young scale hatched out last summer, but the fly certainly did good work in reducing scale.

That the scutellista is to remain with us, there is no doubt. How thoroughly it will keep the scale under control is still an open question. Mr. Mills, of Riverside county, expresses his fears that the comparatively regular hatch of the black scale in that section, coming in the fall, with but little or no fully developed scale in the egg stage in the winter and early spring, will result in the stock of flies not successfully carrying over from one season to another, making a too long hibernating period with but little or no flies breeding during the winter season that can contribute to the maintaining of the stock of flies. It would seem from our own experience in Los Angeles county this winter, that there may possibly be something in this to prove that Mr. Mills' fears are not entirely groundless. I heard Mr. Alexander Craw remark, a short time before he left the State, that he believed it would be a good thing if we had a fairly effective parasite that would destroy the young black scale, working in co-operation with the scutellista.

CLEAN CULTURE OR NO CULTURE.

The practice of keeping the ground on which the orange grove stands perfectly free from herbage and thoroughly cultivated throughout the whole season, year in and year out, has been indulged in by many and is still followed by some. This practice has little to recommend it. A soil so treated soon becomes depleted of its natural fertility and the humus soon becomes used up through constant cultivation and the application of various fertilizers. No amount of fertilizer will do the work it should if the soil once loses its natural body and becomes deficient in humus. In spite of every effort in the line of fertilizing, such a soil will become poor and infertile and the trees will soon show the effects in their unhealthy condition, and the owner will realize it in his diminishing returns.

If clean culture is adopted, humus must be supplied in some way, and the plan used by a number of successful growers in the citrus districts is to cover the ground with a liberal coating of leaves and leaf mold from an adjoining woods. By this means, a mulch and the material from which humus may be formed are provided for the soil. It is far easier to maintain the humus content of soils than it is to replace it after it has been once worked out of them, a fact which it is well to bear in mind.

Humus, one of the most, if not the most important ingredient in any fertile soil, is generally found in inadequate amounts in citrus soils, and any system of cultivation which does not tend to increase the amount or maintain a considerable quantity of this substance in the soil is not based upon scientific principles.

Any piece of ground denuded of its natural covering of vegetation, and so exposed continually to the burning heat of a sub-tropical sun, rapidly loses most of its fertility and becomes dead, lifeless and useless. The soil must not be regarded only as a place for roots to grow and live in, it must be looked upon as nature's food producing laboratory in which multitudes of micro-organisms or bacteria, are busily engaged in preparing food for the plants which grow on it. They fail utterly in the performance of their work if their natural element, a soil rich in humus, is by some means converted into a sandbank. This is exactly the result of long-continued clean cultivation.

* * *

Humus and Its Value.—Humus is a product of the decay of organic substances. When these undergo decomposition in the soil, humus is the intermediate product formed; that is, just before the resolution of the organic material into its component chemical parts. It is probably not too much to say that humus is the most important substance found in any fertile soil and its presence may generally be taken as the index of fertility. The truth of this statement may be realized more fully when we remember the fact that all barren soils are lacking in this substance and the chief difference between a barren and a fertile soil is usually a difference in humus content, not in the mineral ingredients.

The changes which are constantly taking place in soil may be grouped as physical, chemical and biological. The first relates to movement of water, the size of the particles and the mechanical changes, such as those produced by the displacement of the soil particles by animals or the roots of plants. The second includes all changes wrought by the action of acids or other disintegrators of a chemical nature, while the third, in its use here, refers to the changes brought about by soil bacteria. All three of these changes, whether physical, chemical or biological, are intimately associated with the presence of humus.

In regard to the first, it may be premised that soils rich in humus are not solid and compact, but loose, open and better aerated than those lacking humus and that the water-holding capacity is materially increased by a fair admixture of humus. Now, if the ability of a soil to retain moisture is increased by the presence of humus, it follows that all plant food in solution will be held as well and this is an important feature.

Humus contains from three to twelve per cent of nitrogen and this in itself is a fact worth bearing in mind, but it has been ascertained besides that soils rich in humus are usually well supplied with phosphoric acid and potash.

Reference has already been made to the bacteria which play such an important part in the formation of plant food and which are so intimately associated with the work of providing nitrogen for the use of the trees. It may be said that but little nitrogen from those materials in which it is usually found in or supplied to the soil would be available for the trees were it not for their presence, and the bacterial content of the soil, other conditions having been met, is dependent entirely upon the presence of humus.

Hence, it will be seen that humus is a very valuable soil component and is intimately associated with the life activities of a fertile soil. Growers of citrus fruits in Florida use commercial fertilizer in large quantities and in all districts the same practice will have to be followed eventually. Many of the substances applied must undergo certain changes before they can become available. This change from an unavailable to an available state is dependent either upon the action of soil bacteria or chemical agents. Humus forms the media in which the bacteria work, and, furthermore, it holds the plant food when in solution until the roots have a chance to use it. The best and fullest effects cannot be secured from applications of fertilizers to citrus trees unless the soil be plentifully supplied with humus.—From Hume's Citrus Fruits and Their Culture.

RESTING ROSE BUSHES.

All roses, which have been established for more than one year, should now be given a rest until our warmest weather has passed. Do not give any more water until about the first of November, then prune judiciously and start them by a good soaking. When growing vigorously, dig in a liberal supply of stable manure and later, if you wish an extra good growth and crop of blooms feed them sparingly of bone meal.

MOVING PALMS, ETC.

Those who have palms and other evergreen plants which need moving, should withhold water from them until the first week in September when they may be changed to their new quarters.

The secret of success in this autumn moving season lies in this class of plants being at that time in a well nigh dormant state, especially if dependent on rainfall for moisture supply. If shifted in September and given plenty of water, enough warm weather remains to start new root growth before the chill of winter comes. If transplanted later, or too early in the spring, the cold, wet weather will induce decay rather than root growth. Do such work when noted, or leave it until February.

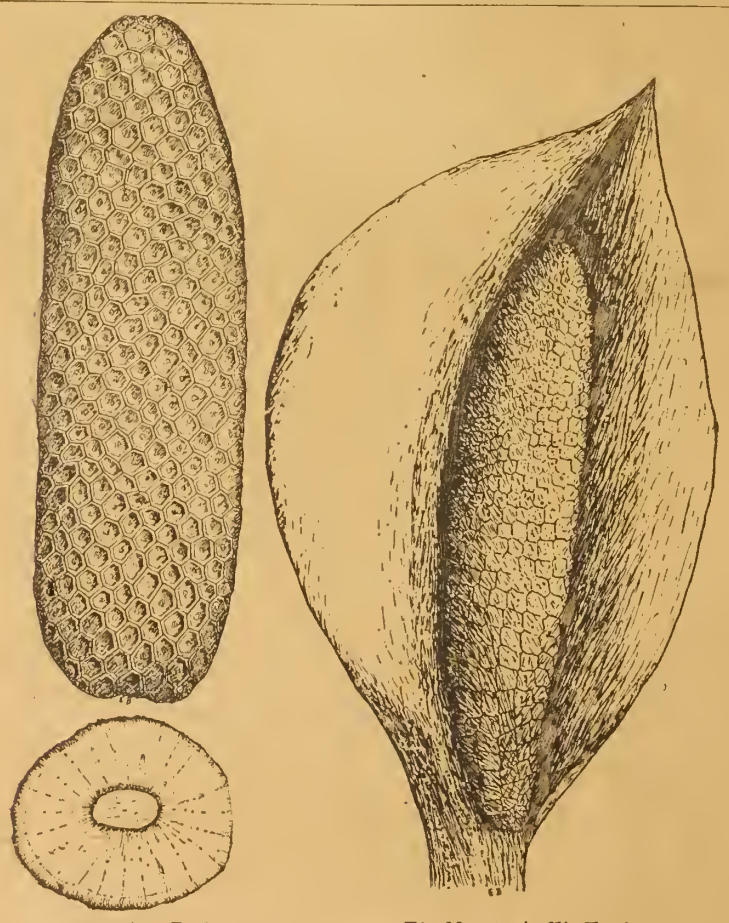
The value of celery to the nervous and irritable person is generally well known, and the laxative effect of fresh, ripe fruits is so desirable that they should be eaten freely daily at meals or between meals.

A DELICIOUS MONSTER.

The name of this curious plant, which is Monstera deliciosa in the botanical world, when rendered into plain English, is as you see in the above heading. It is a very interesting plant to everyone and some little justification exists for calling it a monster, though in every way quite harmless. In California it is a favorite climbing plant for sheltered localities, especially with those who delight in the rare and curious. Though well known in America as a greenhouse plant, its cultivation for its fruit has only recently been attempted,

It has huge perforated leaves, sometimes as much as twenty inches long, and climbs by strong aerial roots of which it seems to have two kinds. The roots by which it grows to the tree are dark brown in color and tough and fibrous in texture, while the others, which appear to serve no other purpose but to feed the plant with air, are much larger, very fleshy and juicy, and present a rather forbidding appearance, as they are spotted, light green and brown; quite like some snakes.

When cultivated for its fruit, it should be allowed to grow on the ground instead of climbing, and this facilitates its propagation as well. Nurserymen and gardeners have been very successful in propagating by cutting the procumbent parent stems in short sections, each with a number of roots attached and leaving them in the position in which they grew until buds and shoots are produced. Whereupon they are transplanted.



The Delicious Part — The Monster in His Hood

"THE DELICIOUS MONSTER"
(Drawings from Life, by the Author)

Notwithstanding its uncanny look it produces a really fine, edible fruit, in taste midway between a pineapple and a banana. In southern Florida considerable attention is being given to this fruit, and it will not be long before it may be obtained in the local markets there, and may eventually find its way into more remote markets. This fruit is difficult to describe—Bailey's Cyclopedia says it looks like a pine cone—our California fruits look more like an ear of corn with densely crowded hexagonal kernels, not disposed in straight rows, but generally spirally arranged.

The real flowers, as in most plants of this order (Aracae), are very small, without calyx or corrola, crowded upon a spadix, as is the case with our well known calla, to which our plant is closely related. Like the calla, this flowered-covered spadix is surrounded with a beautiful white spathe, in many instances quite boatlike in shape. In all there are about a dozen species, natives to tropical America, and all are grown, when obtainable, for their beautiful, and often curious foliage. It really is one of the most unique and interesting plants in the vegetable kingdom, and if grown where the climate is sufficiently warm, will produce fruits of delicious taste. In California the outdoor grown fruits like our bananas, are generally insipid, but in the warmest locations the fruits compare quite favorably with those from farther south.

ODOR OF FLOWERS.

To the vast majority of people, the scent of flowers is simply a pleasure and produces no physical or psychological effect. But there are people so constituted that the smell of certain flowers has a peculiar effect upon them. To some, the scent of hyacinths is most objectionable and their odor produces faintness in others. It is said that Catherine de Medici could not endure the sight or smell of a rose, and Cardinal Guise had a like antipathy to the queen of flowers. With some the scent of the marshmellow flower is said to cause hysteria and the odor of lilies tends to melancholy, while the acrid smell of the marigold induces irritability. The old idea was that the odor of violets encouraged cheerfulness, and rosemary and lavender are still used by old-fashioned people in the country as safeguards against infection and " to keep the moths out." A common form of antipathy to certain plants is the abhorrence with which many people regard any form of fungi. They feel a positive shrinking from this form of vegetable growth and would as soon touch a fungus as they would a snake.

ORIGIN OF PLANTS.

The potato is a native of South America, and is still found wild in Peru. Chili and Montevido. The first notice of it by Europeans was in 1588. It is now spread over a great part of the world. Wheat and rye originated in Siberia and Tartary, where they are now indigenous. Oats are found wild in Abyssinia, and may be justly considered natural to the country. Maize, or Indian corn, is a native of Mexico and other parts of North America. It was not know in Europe till after the discovery and possession of Mexico by the Spaniards. The bread-fruit tree was first found in Otaheite and other South-sea islands. Near the close of the last century, it was transplanted in the West Indies. Tea is found only in China and Japan. The cocoa-nut is found indigenous in the equatorial regions. Coffee is a native of Arabia, and of that part called Arabia Felix, but is now grown in the East and West Indies. The apple is found on most parts of the globe. But in its wild or natural state, it is merely the crab apple, and has been varied and improved by cultivation. The peach is a native of Persia, but in its natural state is small and bitter, or acid, and considered unwholesome. Tobacco is a native of South America and of Mexico. A species of this plant has been lately found in New Holland. Asparagus was brought from Asia; cabbage and lettuce from Holland; rice from Ethiopa and from the East Indies, and onions from Africa and some parts of Asia. The sugar cane is a native of China, and the manufacture of sugar was known there from the remotest antiquity. It was thence carried to Arabia, thence to Egypt, and thence by the Moors into Spain, and thence to the West Indies and Brazil.

General Agricultural Notes

MELON PACKING AT THERMAL.

Now the season is nearly over, growers are already talking about the rest they so needfully deserve. After plowing under the old vines, sowing peas or barley for vegetation, the soil is again ready to be planted for a new crop in the latter part of February or the early part of March. A timely cultivation and irrigation will see a splendid crop of canteloupes about the middle of June. It most surely takes a keen eye to pick the fruit just at the right time, to be shipped and carry satisfactorily such long distances as New York, Pittsburg, and Chicago.

When cantaloupes are ready to be picked they must be fully netted. Should the netting look dull they must not be taken. The netting must be fully raised and must be bright. The creases need not necessarily be yellow. Cantaloupes are picked in common orange picking sacks and put in crates to be taken on a sled to the center of the patch. The patch is picked twice a day all over and picked in two grades, one for east, the other for coast. The coast grade has ripened in such a short time as a half day. The packers size the fruit and pack the same in four different crates, the "pony," the "standard", and the "jumbo" crate and the "special." The pony contains 54 cantaloupes, the standard 45 cantaloupes. A jumbo crate the same as a standard, but, being larger, contains larger fruit; specials are like grape crates and hold 16. Sometimes specials are done away with and packed in the pony crate with an extra half layer.

When the fruit arrives at the loading shed it is closely examined by the inspectors, and should the grower have erred, they are instructed for the better. As soon as the crates are labeled they are loaded in iced cars, which are under cover in the loading shed. Now comes the trouble the cantaloupe shippers have had to deal with ever since the beginning five years ago. When a car has been iced, before loading, the temperature is about 58 degrees. When loaded with cantaloupes the temperature in the car under the roof is about 100 degrees, and on the bottom 70 degrees, a difference of 30 degrees. The puzzle was how to get rid of the hot air in the car. This was accomplished with the Lyon vacaum air blower driven by a gasoline engine. It is placed in the shed the height of the car and is connected with the car, similar to a railroad water tank spout, through a special made ice plug. This blower sucks the hot air out of the car and drives the same air through another car, which is connected with a large canvas hose. Within three hours the car has been brought down to a temperature of 65 degrees. After which the car is reiced and ready to be forwarded.

The very best cars are used for cantaloupe shipments, and the most experienced agents are in charge to see to the icing. The railroads are also hand in hand with the shippers to make a success out of the cantaloupe business, which is only in its infancy. The Southern Pacific, in connection with the Rock Island, have a train which is called the "Expedite," which runs as a section of the regular overland passenger train, making Chicago in four days. Thermal cantaloupes have arrived in splendid shape, solid packed and special New York shipments, which, up to this season, were doubtful.

Much of this success must be credited to M. L. Lyon, a distributor from New York, who represents several firms in large eastern cities who are making a specialty of the cantaloupe trade. The first three cars in New York per expedited freight and Wells Fargo grossed $2000 apiece. Another car by regular through freight, ten days to New York, grossed $1200. Even the second grade melons shipped to Los Angeles and other coast points have netted the growers better than a dollar per crate. Now success in shipping has been reached and taking in consideration that the average yield per acre is 150 crates and the demand more than the valley now produces, no doubt but there is a good future in store for the Thermal Cantaloupe Growers Union.—Wm. Hoogendyk.

THE CABBAGE HAIR-WORM.

The cabbage hair-worm is the subject of Circular No. 62 of the Bureau of Entomology, U. S. Department of Agriculture, the publication of which was made necessary by numerous inquiries in regard to the identity and alleged poisonous nature of a minute worm popularly known during the years 1903 and 1904 as the "cabbage-snake." During the former year the species first attracted attention, but was not considered seriously as it was well known that hair-worms are not in any degree poisonous—in fact they are perfectly harmless and even, to a certain extent, beneficial, as they destroy by parasitism the pernicous coding moth and several species of destructive grasshoppers or locusts. In 1904, however, the subject increased in proportion, the Bureau of Entomology frequently receiving five or six communications daily in regard to this creature. In most cases these were accompanied by clippings gleaned from the daily press. The object of the circular is mainly to facilitate the correspondence of the Department, to place the facts in the case on record and before the public and to correct erroneous reports and mere rumors which have been circulated in regard to cases of poisoning human beings. In only a single case was the name of the person or persons who had been killed by eating cabbage supposed to be infested by this hair-worm given, and the postmaster of the city promptly denied any knowledge of the facts, all efforts that were made to locate the origin of the account being without success. It may be safely assumed that all other reports were equally untrue or greatly exaggerated. In fact, the entire matter was a hoax save for the fact that the rumors were placed in such general circulation that the consumption of cabbage was greatly curtailed, many persons fully believing in the poisonousness of the hair-worm. There is no doubt, on the other hand, that the majority of the reports of damage to the cabbage crop were founded on fact. We have positive knowledge of one of these in Tennessee where fully 85 per cent of the State's cabbage crop was lost in 1904. Similar losses were reported in various portions of Missouri, Iowa, West Virginia, and Virginia. From data at hand it can truthfully be said that thousands of cabbage growers incurred severe losses on account of the unfortunate "scare" due to the unwise circulation of the veriest rumors.

* * *

In support of the statement which has been made by letter by the Department of Agriculture for the past two years, a Dr. Louis Leroy made tests in order to determine whether the hair-worm or "cabbage-snake" possessed any poisonous properties. The usual laboratory animals, rabbits, guinea-pigs, and domestic animals, were fed with the worms, raw and cooked; extracts from the hair-worms were prepared, and the animals fed with them, and the substance was injected hypodermically, the final result being reached, as none of the animals thus treated were affected, that the "cabbage-snake" is entirely harmless and the public rumors and superstitions are fallacies without semblance of foundation.

A SECTION WORTH DEVELOPING.

The Cultivator is in receipt of a letter from Courtney Gilbert of Globe, near Porterville, in which he refers to a valuable foothill section in the upper Tulare river as worthy of more extended knowledge. He says, "We have here a foothill region above the citrus belt say 1500 to 3000 feet altitude, comprising valley and mesa lands which in my judgment comprises the best wine and table grape land in the world. Above Springville is what we call Mountain View country where hundreds and even thousands of acres of the best kind of land is now used for grazing purposes." The writer says regarding this that abundance of water may be secured in spring and early summer. The correspondent has no practical suggestion as to how to get these lands occupied by fruit growers, but takes this means of extending the information of such a vast amount of land being open for improvement.

Reports from Sonoma county go to show that Commissioner Bremner has been most successful in the establishing of colonies of Ephilates and that some excellent work is being done with the codling moth by this little imported friend. Similar good reports are received from a number of northern counties and much hope is felt by apple growers as to the ultimate outcome of the importation of this parasite.

Graft in High Places.—The sad plight in which Senator Mitchell of Oregon finds himself as the result of a deliberate prostitution of his high office, ought to serve as a lasting warning to public men to be honest in the discharge of the duties embraced in public office. Senator Mitchell has been convicted of a violation of the federal law which forbids a senator from accepting compensation for advancing the cases of constituents before the various departments of the government. The evidence introduced in the trial showed that for a consideration he had agreed to use his "influence" with the commissioner of the land office in working through some of the shady games which have been worked by the land looters of the far west, and which, thanks to the vigilance of Secretary E. A. Hitchcock of the interior department, are being exposed, and those implicated brought to the bar of justice.

The charge that other United States senators are just as guilty as Mitchell is not to be accepted as a plea in mitigation. Those who are tarred with this very same stuff may get what is coming to them in due time.

Senator Barton, of Kansas, fell a victim to the same violation of law, and now awaits decision of the Supreme Court of the United States to confirm or set aside the judgment of the Federal Court which convicted him.

The condition in which both these men find themselves challenges both pity and contempt. Both highly honored, might have been a lasting credit to their respective States, and their names might have gone down in the annals of the nation, and in the love of their families for all time as monuments of honor and integrity. That the Supreme Court of the United States will confirm the judgment of the lower courts, and the sentences imposed by them, no well advised person doubts for a moment.

From the Senate chamber of the nation to a cell in the penitentiary is an awful fall indeed, but is the working out of the eternal law of justice meted out to all who disobey the edicts of common honesty among men. No less glaring and sensational are the exposures being made in other lines of business, as for instance, in the affairs of the Equitable Life. Senator Depew, in accepting $25,000 as a retainer fee, simply because he has a great name, as is alleged, favors a doubtful transaction, and may result in his overwhelming and everlasting confusion.

There seems to be a deadening of the consciences of our public men. The burning desire for gold has turned their minds and hearts, until they do not seem to realize the enormity of the offense of graft, nor influence it is having on society. But this cycle of frenzied effort for wealth will pass away, before long, and public officials will come to realize that it is wise and best and popular, as well, to be honest in the discharge of the duties incumbent upon them. In short, there is coming a better day for the world, when wars shall cease, more honorable dealing in business prevail, more attention be given to the cultivation of the good there is in life, and less effort to exhaust our vitality in the strenuous endeavor to amass wealth to the exclusion of every other sentiment or ambition.

* * *

Prime Cause of Discontent.—Sometimes we think the really poor of the world have a reasonable cause to complain at the lavish, foolish and we may say, criminal expenditure of money on the part of the very wealthy.

Multi-millionaires who annually spend a hundred thousand dollars on a single child, and make free to publish the fact to the world, are making anarchists and haters of the rich, by men and women who can barely accumulate enough to keep their souls in the body. We wonder why, at times, this feeling of hatred of the rich is growing, but when we read incidents like the following, we can not wonder much. The story comes from London, that a two and a half year old baby gave the exclusive Claridge hotel a sensation this week which it will not soon forget. He is W. B. Leeds, Jr., son of the steel plate multi-millionaire, ex-president of the Rock Island railroad. Not even an heir to royalty could have more elaborate care or more luxurious service than this little American. It is the wonder of the hotel, the hotel, by the way, where every other guest is a multi-millionaire, and where ordinary lavishness goes without remark.

Young Leeds arrived from Paris with Mamma and Papa Leeds in a big touring car. The parents had tried to get the royal suite for the use of the youngster, but this was already occupied, so they hired two other suites, comprising six bedrooms, two drawing rooms, a good sized and highly expensive slice of Claridge's, half of which was devoted to the infant. Baby Leeds has two drawing rooms, two bedrooms, a sitting room and a bath room. When they reached Claridge's from the continent the Leedses carried forty trunks and most of these contained the wearing apparel and other property of the heir.

The laboring man who reads this, whose child is just as dear to him as the "royal" baby Leeds is to its father, and who toils from dawn to night to give that child the bare comforts of life, without its luxuries, will not be the better contented when he realizes the criminal extravagance lavished on this bundle of babyhood no better than his own.

If people will be such fools, why do they permit their folly to be made public? Do they not see the fire of hate they are kindling in the hearts of thousands of the country's poor steadily grow? Some day, it will break out in one awful conflagration, and nothing outside of God's omnipotent hand can stay the tide of vengeance these suffering poor will wreck on those who they believe have robbed them of what belongs to them.

We have no sympathy with anarchy, or any of its tendencies nor teachings, but we all know something about human nature, and we do know that history repeats itself. It is the Leeds', the Schwabs, and the unholy leaders of the trusts and combines who are spreading discontent among the common people. It is these whom the country has to fear, at the present, more than the anarchists—their day will come later if things do not radically change along the lines the vastly rich are following. They alone are to blame for much of the class hatred in the world today.

* * *

Busy Fruit Season.—If the tourist who has in mind a residence in California will ride out to Toluca, in Los Angeles county, he will be surprised at the extent of the fruit industry. This is not the only place in the county and the State, where deciduous fruits abound and where ranch owners are becoming independent, but it is a fair sample of what a community may do in the way of building up an enterprise where climatic conditions, soil and irrigation or independent moisture, abound, and where the people understand these conditions and make the most of them. In the district of Toluca, comprising but a few square miles, there is a stretch of country probably unsurpassed in California for the raising of apricots and peaches. In this district it is not uncommon to secure a crop of 1500 tons of apricots, and often this amount is greatly enlarged, owing, of course, to the season's rainfall. The rancher realizes, this year, a cent a pound for his fruit green, and the yield, per acre, averages $20. Considering the labor put on the orchard, this is easy money compared to what the farmers in the middle west realize. There they toil from dawn to dark, and are satisfied if they can raise, on the average, 40 bushels of corn, or 15 bushels of wheat, and receive in the market 25 cents per bushel for their corn and 60 cents for their wheat.

The California farmer has a snap in the ease with which he raises his crops, and he is always moderately sure of remunerative prices. Not always so with the eastern farmer, for so many interferences come in, as is the case this year, that he obtains both meager results in crops and inferior returns in prices.

* * *

Peaches.—This year, the ranchers about Toluca will reap a light harvest in peaches. Were the yield normal the crop would reach 3000 tons. It will run about half this amount, or 1700 tons, possibly. One rancher sold the fruit from 750 trees for $1000, which he does not consider anything extraordinary, having done better than that in some former years. Peaches in the Toluca district are selling this year at $31 a ton for clings, and $20 for frees, f. o. b. Naturally, land is valuable in this district, as it is in any district where water is obtained at a depth of 35 to 60 feet, and readily brings from $250 to $300 where the improvements are fairly good.

There are five large drying plants in Toluca, which, when running full, employ 500 hands, these averaging $1 and $1.50 a day. It is a really interesting sight to note this little army of workers, many of whom are children, not over ten years of age, as they fill their trays with a dexterity which many of the older men and women can not attain.

* * *

Walnuts.—The culture of walnuts is a lucrative business in the Toluca district, and the more enthusiastic growers make bold to declare that in quality they are equal to the Anaheim walnuts. Certainly the residents of the district have faith in the walnut proposition, for an increased acreage is being planted this year. We simply call attention to the productiveness of this district to show what may be done by an intelligent, industrious community working toward a common end and favored by climate, soil and water, and a great big amount of faith in their locality and its future.

* * *

Successful Woman Farmers.—Since the government gave out the names of the 120 girls who have won free homesteads in South Dakota, Colorado and Idaho, interest has been aroused to learn how they are succeeding in their venture. A government agricultural inspector has recently paid a visit to twelve farms, the home of twelve unmarried women, to ascertain what progress they are making and the report he files is interesting and full of suggestions. He finds these farms in excellent physical condition, well stocked, clean, with excellent growing crops and a fair start in accumulating certain luxuries which may be had, even on a homestead farm. These young women, some of whom had no experience in farm life, have gone into their work with a zeal which guarantees success from the start, and although unmarried, have so organized their business, on co-operative lines, as to assist each other in their work. They unite in putting in crops, in harvest work and threshing, and vie with one another in making their homes attractive. Here is a new sphere for woman's work which promises success and independence, as well as bringing with it health and happiness.

It's a far pleasanter occupation than school teaching, or bookkeeping, or clerical work of any kind, because it will bring competence, without mental strenuousness, which, after all, is the consideration most desired.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The prune crop in the Pajaro valley, while not heavy, promises to be of fine size and good quality.

At Lemon Cove, Tulare county, a large citrus packing house will be built at once by the Kaweah Lemon Co.

Over two thousand acres of soft shell English walnuts were set out in the La Habra district, in Orange county, this year.

Toluca valley apricot growers are rejoicing over the fact that this year makes the fifth heavy apricot crop in succession.

The Limoniera Company, at Santa Paula, shipped from its ranch seventy-one carloads of lemons during the month of June.

The work of drying apricots in the Santa Clara valley, Ventura county, commenced last week. While the fruit was slow in ripening, yet the crop was very good.

A dispatch from Orangevale, Sacramento county, states that fifty to seventy-five per cent of the grapes and fifty per cent of the plums were ruined by the recent hot spell.

The Sonoma County Farmer of last week states that apples in that district were considerably damaged by the excessive hot weather; also that hops were checked in their growth.

More than three hundred and fifty workers are employed cutting apricots daily at the Gregory drier west of Redlands. The output of this drier is expected to run close to fifteen hundred tons.

The apricot crop in the Suisun valley was all picked and dried by the end of last week. Owing to the hot weather the week previous, the yield was considerably less than had been anticipated.

H. P. D. Kingsbury of Redlands, announces that he will enlarge his marmalade and preserve factory and also the orange packing house owned by him and occupied by the Golden State Orange Association.

The returns of the May shipments of the Late Valencias made by the Whittier Association show a net price of $2.05 for choice packed. The average price for the entire month's shipments was $1.88 per box.

The late spell of hot weather had a disastrous effect upon the berry crop through nearly the entire northern half of the State. While some sections were only lightly hit, yet in others the crop was almost destroyed.

Thomas Hooker, of Highland, picked 3052 field boxes of Valencia orange off the trees on five acres. For these he received $1740 net. This is 57 cents per field box, or $358 per acre. Which same is not a bad showing.—Redlands Citrograph.

The big fruit cannery at Healdsburg was started in operation this week by the Healdsburg Fruit Association. A new invention has been placed in the cannery by which the peaches are pealed by steam in place of being done by hand by women as heretofore.

Wineries are bidding $10 per ton for Sultana grapes at Orosi. Growers claim that it will pay better to convert them into raisins owing to the shortage of Muscat grapes. Watermelon growers at Orosi say that the crop will be very short, owing to the ravages of a small black bug damaging the vines.

G. Harold Powell of the United States Department of Agriculture says he has conclusively demonstrated from experiments in the Sacramento valley that ripe fruit, well refrigerated before shipping, will arrive sound under ordinary railroad refrigeration even after being from ten to fifteen days en route.

Our correspondent in Sonoma county writes us that what is called the Vine Hill district, west of Santa Rosa, bas a good crop of prunes this year. Some sales of green fruits are reported at $29 and $30 per ton, to the grower. A very fair crop of apples is reported in the northern end of Sonoma county, drying and shipping of the fruit now being in progress. Growers get $8 per ton for apples, for drying; packed 4-tier Gravensteins bring about $1.10.

The Highland Orange Growers Association at an annual meeting recently held, re-elected Robt. Thompson as manager for the next year. The report as filed shows that the season for the association has been a most successful one. The association has paid to the members $42,799.05 net, receiving $1.08 per hundred for every navel orange that has been hauled into the house, which amounted to 3,958,226 pounds. New additions are to be made to the packing house.

The Pomona Times states that: "The San Antonio Fruit Exchange has already received to date for fruit shipped $825.000. There are over 50 cars of fruit from which the money has not been received and 150 cars of Valencias and lemons yet to ship. The total receipts of the San Antonio Fruit Exchange for the previous year were only $763,000. The manager expects the total for this year will be about $950,000, depending upon the number of cars of lemons and Valencias that will be shipped during this and next month."

A. R. Sprague of Sacramento says that he has invented a machine by the use of which an iced car filled with hot fruit, which ordinarily retains its heat for three days after shipment, can be thoroughly cooled in a few hours by a stationary apparatus applied to the ice tanks and drip tubes of the car. He says that a carload of peaches, half of which were overripe, was thus cooled at Oleander, Fresno county, July 1, and sold at auction in Chicago July 10 for $1132, every box having arrived in good condition.

The Highland Orange Growers' Association declared its last dividend last week, when $5500 was divided among the thirty-five stockholders. According to the association's annual report, $42,799 net has been paid to the members—$1.08 per hundred has been received for navel oranges, of which 3,958,226 pounds were hauled into the packing house in the season. Including all expenses, the packing has cost 28.94 cents per box through the entire year. The shipments of this association have amounted to 270 cars, of which thirty were lemons.

AGRICULTURE.

It is reported that hop picking in the Durst hop yards near Wheatland will commence about August 20th.

The last of one hundred and fifty cars of the cantaloupe crop of Coachella for 1905, was shipped last Saturday.

The Pauba ranch, in the southeastern part of Riverside county, was sold last week to Harry L. Heffner, of Arizona. The ranch consists of 38,000 acres of land and valuable water rights.

Beet growers commenced hauling their product to the Oxnard factory last week and on Monday of this week the big factory commenced the 1905 campaign, which is believed will be the record breaking run of its history.

Three hundred thousand sacks of grain is the estimate for this year's corp in the San Diego country on the coast side. Of this amount, the Fallbrook country will have nearly 150,000 sacks, and Escondido valley will have about 115,000 sacks, and the El Cajon valley nearly 50,000 sacks.

The Ventura Board of Trade will send two thousand sacks of lima beans and two thousand sacks of beet sugar to the Lewis and Clarke exposition to be distributed free on Ventura County Day. These sacks will not be of the usual size, only being large enough to contain a sample of two of Ventura's staple products.

The Hollister Free Lance reports that a Mr. Champaign has forty acres of chili peppers growing in the San Juan valley, the yield of which promises to be large. Offers for the crop have been made which will give a handsome return for the investment. Mr. Champaign intends setting out one hundred acres of chilis next season.

The grasshoppers in the vicinity of Wheatland are reported to be becoming troublesome and the farmers are making a decided effort to get rid of them. P. C. Dresher has built a large machine on runners about nine feet wide and sixteen feet long, which is drawn by horses through the field. The grasshopper fly against it and fall into the trough of oil which kills them.

The big Dixie Thompson ranch adjoining Ventura will not be sold, but will be subdivided into small tracts and leased for a term of years to farmers. This ranch consists of 2500 acres of fine bean land and is known as the largest lima bean ranch in the world. The owners announce that they will put in a pumping system on the ranch which will cover every acre with water.

LIVE STOCK.

A new creamery has been started near Tehama.

M. J. Groshong & Co. have opened a poultry supply store at Burbank and report a good business from the start.

Wm. Hanna, the owner of the creamery plant near Pleasanton, recently destroyed by fire, has made arrangements to rebuild.

Several carloads of fat cattle were shipped from Santa Maria to the Cudahy Packing Co., at Los Angeles, last week.

Joe Muscio, a dairyman and cattle rancher near Los Alamos, has decided to put in a big irrigation plant to irrigate part of his ranch.

The Newhall Land and Farming Co. shipped 1500 head of fat steers from Santa Maria to the Western Meat Co., in San Francisco, last week.

It is reported that Messrs. Ahler and East, of Santa Ana, will build two creameries in San Luis Obispo county, one at Cambria and the other at Cayucos.

Great forest fires occurred in the upper part of Yuba county last week, burning over hundreds of acres of timber, besides causing great loss of cattle and other live stock.

A stock company last week bought the five hundred acre farm of the G. Sieber Co., near Marysville, and will engage in the dairy business in a large way. Three hundred cows will be milked and a skimming station erected on the ranch. The price paid for the ranch is said to have approximated $200 per acre.

The old Dairy Exchange of San Francisco, which suspended several years ago, has been started anew under the original charter. About twenty-two firms, brokers, etc., have joined the organization and adopted, with a few minor changes, the plan of organization recommended by the committee that had been selected at a previous meeting.

The repeal of the quarantine against American sheep and cattle which has closed the ports of Australia to breeders and stock men of this country has resulted in a demand from the Australian ranchers for American stock. Henry Glide, who has a cattle and sheep ranch near Sacramento, last week sold a nice bunch of French Merino sheep to an Australian for breeding purposes. Mr. Glide recently shipped sixty head of sheep to South Africa and another large shipment will be made to Honolulu next week. He exports annually about five hundred head of sheep to France, England, Germany and Africa.

MISCELLANEOUS.

A carload of honey was shipped from Redlands to the East last week.

The forestry school has been in session for the past ten days at Idyllwild.

The bee men about Elsinore report the disposing of a part of their honey crop at the price of ten and a half cents per pound.

The official call has just been issued for the meeting of the National Irrigation Congress, to be held at Portland commencing August 21st.

A cold storage plant is to be built at Port Kenyon, Humboldt county, at once. The building will be sixty by one hundred and fifty feet in size.

The State Superintendent of Public Instruction reports that the number of school children between five and seventeen years of age in California this year is 419,275, an increase over last year of 11,871.

The Chamber of Commerce at Eureka have agreed to furnish a bonus of $3000 to the District Fair Association if they will hold a fair in Humboldt county this fall. This amount the directors of the association believe will save them from loss equal to that they sustained last year.

C. H. SESSIONS, ASSOCIATE EDITOR

FEEDING FARM HORSES.

The difficulty of keeping horses in good condition during the hard work of mid-summer is a problem for the farmer who wishes to crowd his team up to its capacity. The following contains some good suggestions, which are noted in the O. J. Farmer:

There is no hard and fast rule that can be laid down as the only proper way to care for horses during the summer months, when they are hard at work. Local and individual conditions enter as factors, and in a measure determine the most practical way. There are, however, some fundamental principles concerning the feeding and care of horses that may be profitably discussed.

Almost everyone has noticed a great difference in the general thrift and condition of horses used on different farms. It is quite evident that some men through their system of feeding and care are able to keep their horses in first-class condition while doing a maximum amount of work, while other men fed their horses at a greater expense and yet maintain them in poorer condition.

* * *

Feeding Horses at Work.—The problem of feeding the horse when at work is quite different from the problem of feeding the pig or steer. The horse is fed for the production of energy, while the pig and steer are fed for the production of new body tissue. The feeding of the horse can more properly be likened to the firing of a steam engine for the production of energy. Before there can be any work done by the engine enough fuel must be supplied to raise the temperature of water to steam. Additional fuel will convert the engine from an inert piece of matter into one that can do work. The same principle is true with the horse. A certain amount of food is necessary to repair waste and maintain the animal body. Additional food added to the maintenance ration will enable the horse to do a certain amount of work and yet maintain his body weight, or, in other words, not lose flesh.

* * *

General Rule for Feeding.—A general rule is that a horse requires one pound hay and one pound grain per 100 pounds live weight when doing medium work. At hard work the grain part of the ration should be increased up to 1¼ pounds per 100 pounds live weight, in order to have the animal maintain his body weight. If the horse is doing such severe labor that he is losing flesh and it is considered necessary to increase his grain above this point, which is seldom necessary, the quantity of hay should be decreased. Great care should be exercised in making this change, for there is then danger of disorder of the digestive system. The more concentrated a food is, within proper limits, the less the percentage of energy needed to make it available. When horses are doing light work less food will be required, and the percentage of roughage to concentrates may be increased.

* * *

Observe the Laws of Health.—In order that there may be no disorder of the digestive system, the laws of health must be observed. It has long been known that the stomach needs a large supply of blood when called upon to perform its function of digestion, and in order that the process may be carried out undisturbed the horse should not be worked soon after a heavy meal, as that would call the blood elsewhere in the body and arrest digestion, which may cause indigestion or colic. As a horse does not have long for the consumption and digestion of food in the morning and at the noon hours, he should not be given a heavy feed at these times. A good plan is to give a light feed in the morning and at noon, and a heavier feed at night, when the horse has plenty of time to consume and digest it. Those who have used both horses and mules know that a mule will thrive better than a horse under careless or unskilled treatment in feeding. The mule seems to have sense enough not to gorge himself with feed in the morning or at noon, but consumes a large part of his ration at night.

* * *

Division of Daily Ration.—A good rule is to give 3-10 of the grain in the morning, 3-10 at noon and 4-10 in the evening. The combined amount of hay fed at the morning and noon feeds should equal that fed in the evening. Where a 1200-pound horse is being fed in the above way he would get three pounds hay and 4.5 lbs. grain at morning and noon and six pounds hay and six pounds grain in the evening. Some successful horse feeders divide the grain into three equal parts and feed all the hay in the evening, none at morning and noon. Of course the horse will not eat all of the hay at once, but will consume most of it before the next morning. On Sundays and idle days the grain should be reduced one-half of the total amount if the horses have been consuming large amounts of grain. This is necessary for the prevention of "azoturia," which is likely to occur as a result of heavy feeding of grain when idle.

CLEAN BUTTER PACKAGES.

Regarding the advantage of neat butter packages a writer in the Creamery Journal writes:

"All creamery men are desirous of getting fancy prices for their butter, but many evidently do not realize that it requires at least ordinary care to secure these prices.

"The value of all foods is materially enhanced by marketing them in attractive packages. Manufacturers appreciate this so thoroughly that many common products, which have hitherto been sold in bulk to retailers, are now furnished in neat and attractive packages, which the retailer is not in a position to provide. It is the exterior by which we commonly judge things, and when we find a lot of dirty, poorly-covered tubs we at once conclude that they contain an inferior quality of butter.

"Frequently it happens that clean tubs are hauled to the station in a filthy wagon box. Do not permit your butter to be transported thus, but clean the wagon box before loading. All this will usually require is a broom,

24 YEARS WEAR NO REPAIRS

SEPARATOR FACTS

43 YEARS WEAR 75¢ REPAIRS

Just facts—that's all you want. Facts can't hurt you nor Tubular Cream Separators. Facts prove Tubulars outwear all other makes five to ten times over.

On August 2d, 1904, we started a No. 9 hand driven Dairy Tubular, rated capacity 900 lbs. per hour, on the hardest test a separator was ever put to—an endurance test to last until the wearing parts give way. This Tubular has now run 50 hours a week for 43 weeks—and is still running. Every week of this test is equal to a year's service in a ten cow dairy. No other separator made could stand such a test.

24 Years' Work—No Repairs		43 Years' Work—75c Repairs	
Hours run	1,200	Hours run	2,150
Pounds separated	1,080,000	Pounds separated	1,935,000
Turns of crank	8,155,760	Turns of crank	5,652,070
Turns of bowl	1,152,000,000	Turns of bowl	1,864,000,000
Oil used	8 quarts	Oil used	5¾ quarts
Time oiling	About 4 min.	Time oiling	About 7 min.
Time adjusting	None	Time adjusting	10 min.
Repairs	None	Repairs	75 cents

After 24 weeks, the balls in the frictionless bearing supporting the bowl showed wear. This was natural, for each had rolled over 32,000 miles. Renewing balls cost only 75 cents and ten minutes adjusting, yet made this Tubular as good as new. All Tubulars are equally durable. Catalogue P-260 tells about them. Write for it today.

THE SHARPLES SEPARATOR CO.

Toronto, Canada West Chester, Pa. Chicago, Illinois

MEALFALFA

Reg. U. S. Patent Office

For CATTLE, HORSES, HOGS and POULTRY

The Food for Dairy Cows In its form you can get the most favorable results in mixing. Use about 50 per cent with other grains. When wet it makes a huge, bulky food, keeps cows in fine condition and increases the flow of milk.

Mealfalfa is a green protein food and a dilutant that cools the system. It is a very essential food for calves. Being a protein food it makes blood, bone and muscle, causes them to grow rapidly, makes them fat and gives a better grade of veal. Mix with skim milk and you will get a wholesome food of bulk.

☞Get a trial order from your dealer and save money on your feed.
☞If your dealer does not carry Mealfalfa, write us for free sample, prices and particulars.

Stockton Mealfalfa Co.

When writing advertisers mention Cultivator.

a few pailsful of water and three minutes of time.

"In speaking of butter tubs it is well to call attention to the importance of storing them in a clean, dry place. Mould will not develop in them so long as they are kept dry. It is likely, however, that the pores of the tubs contain mould spores which are readily destroyed by soaking the tubs in water about an hour and then steaming several minutes. Many make the mistake of steaming the tubs when dry, which renders the steaming less efficacious than in the case where the tubs have been previously soaked.

"Another aid in the preventation of mold is to give the tubs a thin coating of salt before lining, and to soak the liners in strong brine, which acts as a disinfectant.

"It is well to remember also that if the creamery is damp and poorly ventilated, and possibly shows of mold, the tubs may be infected with mold germs over night if the steaming and soaking has been done the preceding afternoon, as is frequently the case. If a tank is used for soaking the tubs the water in this tank should be changed daily and the tank kept scrupulously clean, to insure against contaminating the tubs with mold germs."

CAPTURING OF COYOTES.

The Department of Agriculture has just issued Farmers' Bulletin Number 226, on "The Relation of Coyotes to Stock Raising in the West." From which we take suggestions regarding destruction of this pest. There are, however, statements in the book showing the vast advantage this animal has been to many agricultural sections in the keeping down of jack rabbits and other pests which are even worse than the coyote. But, in the whole, the report considers the coyote of more damage than advantage. The average of all the Western States is said to show a loss to sheep raisers of over five per cent. Of course, the vast losses to poultry raisers are also well known. From two methods, that of poisoning and the use of traps, we quote:

* * *

Use of Poison.—Poison has probably killed the greatest number of adult animals, and in parts of Mexico has almost destroyed some of the species, but no such success has followed its use in the United States. Strychnine is the favorite poison, and is, all things considered, the only one suitable for the purpose.

"In the use of strychnine, the dry crystals of strychnia sulphate are generally preferred, as the poison in this form is really soluble. The poison is inserted with a knife in small chunks of meat or in the carcass of some animal and left upon the prairie. The meat should be handled as little as possible, and if small pieces are used it is best to distribute it from horseback along trails used by the wolves. The animals are very cunning in detecting and avoiding poisoned meat, and some hunters are successful in allaying their suspicions by burying the bait.

It should be remembered that poisoned baits are as likely to attract dogs as wolves. When poison is to be used the entire neighborhood should be informed and valuable dogs should be confined until the operations are over and all uneaten baits destroyed.

* * *

Use of Traps.—Coyotes are not easily trapped. Some skill and a good knowledge of their habits are requisites for success. They travel in rather well defined paths and usuallly hunt against the wind. Having a keen sense of smell, they easily detect the tracks of men, and if they have had previous experience of traps or guns they are suspicious of danger. In the wildest parts of the country remote from settlement they are more easily trapped. The chances for successful trapping decreases with their familiarity with man, so that there is little probability that the process will ever have much effect on their numbers.

"A number three steel trap is generally used. A suitable place is selected along a narrow path or trail and the trap is sunk in the ground level with the surface and concealed with fine grass, leaves, or other material that will harmonize with the surroundings. At the same time care is taken that the material used shall leave the jaws of the trap free to spring clear of the covering.

"The trap should be fastened to a bush or stake, or, if these are not available, to a clog. For the last a pole lying on the ground is best, since it may be utilized without moving it or disturbing the surroundings. If the trap is anchored to a bush or small tree the chain must be securely fastened with snap or wire. A stout stake over which the ring will not slip, driven out of sight into the ground, is better. Every part of the trap and chain is covered, and the ground left in as natural and undisturbed condition as possible.

"Any kind of fresh meat will do for bait—rabbits and other small rodents are often used, but larger baits seem to be more attractive. It is also of advantage after setting the trap to make a "drag" of the bait for a quarter to a half mile, at the end of the rope from the saddle horn, and finally to fasten it to a bush or stake close to the trap, or cut it in bits and scatter all around the trap, so that not all can be reached by the coyote without walking over the trap. The skill of the trapper and the situation of the trap will determine the best arrangement. The suspicion of the coyote is lessened apparently after following the bloody trail of a well-planned drag.

"Before setting the trap many trappers rub their feet and hands on a skin or some strong-smelling meat or carcass to conceal the human odor. Oil of anise or rodium is sometimes used for the same purpose. Any strong odor is likely to attract the attention of the coyote and allay suspicion. Care must be taken not to spit on the ground or kneel or throw down any clothing in the vicinity of the trap. A good plan is to set a line of traps and leave them for a day or two, and then go the rounds with a horse and drag and bait the traps without dismounting."

WHEN TO BREED HEIFERS.

A correspondent from southeastern Minnesota wants to know when to breed his heifers. He is of the opinion that they should be three years old by the time they drop their first calf, but says that many of his neighbors have them come in when they are two years old. He would like to get our opinion on this question.

Whether to have the heifers come in when they are two or three years old will depend somewhat upon the breed of cattle our correspondent is raising, his method of feeding, and the individuality of his animals. The earlier heifers intended for the dairy

are bred, other things equal, the better cows they usually make. This does not mean that dairy heifers should always come in at two years of age, but it does mean that if they are large and vigorous it is better to make them come in at the age of two years than to wait another year. As a rule, Jerseys, when properly cared for, have practically matured when they are two years old, and it is, therefore, better to have them come in at that time.

We are aware of the fact that there is difference of opinion on this point. Some claim that a heifer should be matured before she is bred, while others claim that she should come in at that time. We agree with the latter view. A great many successful dairymen breed their heifers before they are matured with good results. Holsteins do not mature quite so early as do Jerseys, consequently a Holstein heifer should be about six months older when she drops her first calf than a Jersey. Our correspondent and his neighbors may all be correct from their own standpoints. One often sees a man whose cattle are as large when they are two years old as another person's cattle are when they are three years of age, in spite of the fact that they are practically of the same breed. The reason for this lies almost wholly in the method of caring for them. It is important that young stock should be kept growing from the day of birth until maturity, and if they are, a good rule to follow is to have the heifers come in about the time they mature.—Bulletin.

AN UNJUST METHOD.

The course taken by the mayor and health board of Los Angeles in giving the conditions in several of the dairies about the city was, we believe, unwise and even unjust. The mayor and members of the Board of Health made the rounds of the dairies and found that, which is too often true, many of the dairies were unclean in several particulars. Others were careless, especially as to allowing flies to be too free about the milk house and other features were discovered which were not to the credit of the dairies investigated. It may possibly be, so far as we know, that the findings of the mayor and his board were absolutely correct. It is not the mission of the Cultivator to appeal for a lowering of the conditions in dairies which are supplying milk to cities or cream to creameries. The injustice of this method was in that it injures the entire dairy industry and does not necessarily correct what was found to prevail in some dairies. The health board has it absolutely in its power to deny the dairymen the privilege of selling their product in this city if they are careless or unclean in their methods. That could quietly have been done, or at least some method taken by which the desired end could be accomplished without raising a great hue and cry and using the newspapers to accomplish that which the board should have had nerve enough to accomplish for itself in the regular and proper way.

We say it injures the entire industry which it does by the creating of the feeling, especially at such a season of the year as this, in the minds of many consumers that restrains them from consuming this most wholesome and desirable food. This, as we have said before, injures the entire industry, for the public does not stop to discriminate between innocent and guilty and classes the whole collection of dairymen with those who may be unclean.

VELA HASTINGS.

As will be noted in another column, C. W. Leffingwell, Jr., of Whittier, is offering for sale Vela Hastings, the cow which made the remarkable record spoken of in the Cultivator a few weeks ago.

Regarding this cow, Mr. Leffingwell writes:

"In offering for sale our grand cow, Vela Hastings, we are marking an epoch in the development of our herd, as we have now reached a stage where we have all the pedigreed cows in milk for which we have room and it will be our policy from now on as our heifers develop to make occasional offerings of matured cows. To prove to the public what these cows can do we have been subjecting them for some time to yearly authenticated butter fat tests, it being our desire to give full value for money received and to base our prices on what our stock is actually worth so that every buyer shall be more than satisfied.

Vela Hastings is the first to complete her year's record, which entitles her to registry in the Register of Merit maintained by the American Jersey Cattle Club. Considering the small amount of grain consumed during this record it stamps Vela Hastings as a remarkable producer and she is today at her prime, full of health and vigor and giving more milk than she did last year while making her record. We shall be disappointed to see this cow go, but we have her daughters and granddaughters in our herd, which we believe will prove better even than she and for which we must make room. As to the matter of price, Vela is good for a number of years profitable work and her first calf by Sargent Fox will be well worth the purchase price. We have five heifers by this bull, and while they are not yet old enough to be in milk, they are of uniformly beautiful type with remarkable udder development and rangy, milky look; we feel safe in saying that if exhibited in the East they would create a sensation, and predict that when they come in milk they will demonstrate the value of Sargent Fox as a dairy sire.

We have had to buy, test, and discard a good many cows to secure such performers as Vela Hastings and any one who wishes to get a safe start in the Jersey business cannot afford to let this opportunity go by. In addition to her performance, Vela Hastings' blood lines are very valuable for a foundation, her sire being Paron, son of Diploma, the greatest of Combination bulls, and her dam a tested daughter of Southern Prince, one of the greatest Coomassie bulls. Surely if Southern California breeders appreciate a grand individual with good blood lines and splendid proven performance, Vela Hastings will not remain long for sale."—C. W. Leffingwell, Jr., Whittier.

ARE THEY SEVEN PER CENT MILKERS?

There were some rich milking Jerseys in the butter test on the Island in May, 1904. The gold medal winner made a pound of butter from 11.34 lbs. of milk, her yield being 3 lbs., 2¾ oz. butter for the day. The fourth prize cow made a pound of butter from 11.34 lbs. milk, her yield being 2 lbs. 12¼ oz. butter. The fifteenth prize cow made a pound of butter from 11.24 lbs. milk, her yield being 2 lbs. 1¼ oz. butter. Another cow made a pound of butter from 12.27 lbs. milk, and seven others required between 13 and 14 lbs. of milk to a pound of butter. The gold medal cow had calved four months prior to the test, and gave 36 lbs. of milk. Those who do not believe there are Jersey cows which will test over 7 per cent fat when flush will be entertained by figuring this out.—Jersey Bulletin.

GRUBS IN CATTLE.

Replying to a query as to eradication of grubs or warbles in cattle, a correspondent in the Dakota Farmer gives the following, which is simple and easy to test: Fill a sewing machine oil can with turpentine and insert it in the opening and inject a little of the turpentine, and we find we never have to use it twice in the same place. It acts like a charm. The grub shrivels up and comes out without any help. I think this a much better way than using a hot knitting needle or squeezing them out, as the cattle do no notice it at all.

POULTRY BREEDERS' MEETING.

The Poultry Breeders' Society of Southern California will be held at Liberty Hall, 107½ North Main st., Los Angeles, Tuesday evening, July 25th. C. P. Glogger will talk on "Modern Poultry Culture;" S. M. Butler will read a paper on "What Fancy has done for the Utility Man," and a short talk will be made by D. C. Johnson, of Whittier. Incidentally, we suppose there will also be some talk about the coming show and such other matters as may interest poultrymen.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

MOULTING.

"See the feathers in my yards," said a friend to me, " and they were all cleaned out yesterday!" "Good for you!" was my reply. "You will have an early moult and plenty of eggs in the fall!"

Now, my advice, given as a result of my own experience is, examine your hens carefully, discover those whose feathers, like ripened fruit, are ready to fall, put those together in one yard and feed them the food that will loosen their feathers and make the new ones grow. Of course you can feed your whole flock in this way, but the results will not be so satisfactory, because the feeding for feathers will not have the same effect on all of them. Last year I gave at this season the account of the experiments on the moult at some of the government experimental stations. There it was found that by making the fowls fast for two weeks, and then feeding very liberally that it hastened the moult; this is usually called "forcing the moult."

I believe in assisting nature; do not believe in forcing nature; there is a difference in this, and for several years I experimented on these lines. We all know that when a hen has been sitting on eggs, she does not eat much, and grows poor, some hens more so than others. After the chickens are hatched, some hens continue thin and poor, calling the chicks up to feed and neglecting their own meals, some eat heartily, as soon as the chicks are satisfied, and these last in about two, or perhaps three weeks, commence to moult and go through either a partial moult or a full moult, according to the season. On these grounds the experiment station and some private individuals, decided that the way to force the moult was to copy nature; starve the hens for a period of two or three weeks as if they were sitting, giving them only one meal a day, and that a light one. This was the plan and it was found to work well in most cases. I tried it for three years in succession—my hens were great layers, bred to lay, and were well and liberally fed. It was July, some of the hens had been sitting on duck eggs, guinea eggs, peacock and turkey eggs, four weeks. I considered that this length of time was sufficient starvation. Some of them seemed poor in flesh, others were still heavy. The chicks and ducklings went to the brooder, and the hens by themselves into a large yard with shady trees, a good scratching pen and clean, comfortable roosting house. Here I began to feed them a little more liberally each day, giving them grain in the scratching pen, equal parts of wheat, Kaffir corn, rolled barley, and rolled breakfast oats, one handful for each hen in the morning thrown into the hay. At noon all the green clover they could eat and an ounce of green bone cut fine. At night a mash of two parts bran, two parts corn meal, one part breakfast oats, half a part meat meal, and one third of the whole green cut clover. To this I added a cup full (about ten per cent) of linseed meal, a cup of charcoal and a tablespoonful of salt and pepper. I had some sunflowers and threw the heads full of seed into the yard for the birds to peck out the seeds, and I occasionally substituted cottonseed meal for the linseed. In a week or ten days about half of the hens were shedding their feathers freely and began to look very rough, the others began to lay and showed no symptoms of moulting. Those that shed their feathers quickly, got their new feathers also rapidly, and in about a month were clad again, whilst those that were laying shed their feathers slowly and when the new feathers commenced to grow they quit laying and all rested for about three weeks. All began to lay early in the fall.

By this I learned that some of my bred-to-lay hens would lay even whilst moulting; also that when the feathers are sprouting very few hens will or can lay because the surplus food (beyond that which supplies nourishment for the body) goes to making feathers instead of eggs. It is very rare that a moulting hen will grow fat, but by feeding the old hens plenty of fattening food, the old feathers will ripen quickly, fall off, and the new feathers will be stimulated to grow rapidly and when fully grown the energy developed by this feeding will be turned into eggs.

I feel sure that by "judicious" feeding we can greatly assist the moult. I would like to advocate two weeks of "judicious" fasting, but last year about moulting time I gave a synopsis of the experiments in one of the government experiment stations advocating the starving system and, not long after, I received a letter from a friend reproaching me for my cruelty, telling me that her neighbors were not feeding anything at all to their fowls, in consequence of my article, and she was so broken hearted over the dumb brutes suffering that she was feeding them herself. A poultry breeder, an old one, met me and said, "So and so, who is always very economical in his feeding, and keeps his fowls just alive, but they don't lay, is now starving them because he says you advocate it;" he laughed, and added, "the poor hens, if they survive, will never recover or amount to anything." The old breeder is a very successful man and a very generous feeder. He afterwards went to see these poor hens and he told me, confidentially, that he did not think an expert could bring those hens out fit to show, adding "I would not take them as a gift."

So this year I feel afraid of advising any one to starve their hens, and will only say feed all the green feed, vegetables, clover, alfalfa, fruit, that you can get them to eat, and cut off all the corn, cracked corn, Kaffir corn, or Egyptian corn, and give a half feed, or even less, of dry bran, alternating with whole oats soaked in hot water for an hour of an evening. Keep this up till the middle of August and then begin a liberal feeding of the more fattening foods.

When writing advertisers mention Cultivator.

I want it clearly understood, however, that this starving on green food, is only for the yearling or two year old hens that you are keeping over for layers or breeders for next year. Do not starve the pullets; give them from the time they come out of the shell till they begin to shell out eggs of their own a generous amount of feed.

After the hens that have moulted commence to lay you will have, with American breeds, to again alter the feeding, if you do not they will either get too fat or will moult over again. Feed less corn in any shape, that is either cracked or as feed meal. Let the largest part of the feed be wheat or its byproducts, or oats, then barley and only a smaller amount of corn.

* * *

EDITOR'S QUESTION BOX.

Little Turkeys.—(C. R. C.) Thank you for kindly offering to give me any help I need with my poultry. At present my only trouble with my turkeys is that they seem to get chilled and get lung trouble. I have lost six in that manner so far. Once they start to droop their wings they never seem to live long. I have tried dosing them with quinine (½ gr. at a time) and liquizone (a lung remedy) but it was of no avail, in some cases they started with bowel trouble. I cured them of that, with soda and water, and castor oil, but they died soon after. I keep them well dusted with lice powder.

Answer.—When little turkeys or chickens droop their wings, it is a sign of lung trouble; they have taken cold. Prevention is better than cure. You must find out why and how they are taking cold. A perfectly tight box is not good for turkeys; they must not sleep in a draught, but they must have plenty of air. I put mine in a box or coop with one side completely out; they are sheltered from the night breeze and have a good roof over them and tight sides to the coop, but the front is open. Perhaps your mother hen has deserted them and they take cold at night. The best way to prevent that is by keeping her (if a chicken hen) shut in the coop and out of sight of the other hens. Liquizone would not be good for them. The best thing for little turkeys is finely chopped onions to prevent and cure a cold. Rice boiled in milk, with a tablespoon of cinnamon added to each pint of milk is also a very good cure, especially when the bowels are affected. But prevention is the best cure of all, and regularity in feeding. One day's forgetfulness, or one day's neglect in letting them get out among your Indian Runners and eating their food, is enough to start the trouble and when once started it is very difficult to eradicate any disease amongst little turkeys. It is easy to forget! You see I am a grandmother and know by experience how hard it is for boys to remember—but perhaps you are not one of the forgetful boys.

* * *

Turkeys.—(E. D. C.) I take such pleasure in reading your articles on turkeys that I must write and ask your advice as I think you are the best authority on raising turkeys I know. I followed your directions last year and was quite successful. This year I thought I would raise them on a larger scale but have almost failed. I have eight hen turkeys and one gobbler. They laid one hundred and sixty eggs and out of that number thirteen only hatched and I have six that will pull through all right I think. I got another gobbler and the second lot of eggs hatched fine. What do you think about keeping the turkeys confined to yards ninety by twenty-five feet during the laying season and a few weeks after hatching, then turning them out on a range of eight hundred acres? I did this on account of so many varments destroying the eggs and hens too. The yards are fenced with wire netting, have running water in each, alfalfa, clover and grass. I kept plenty of lime, charcoal, grit and ashes and some green feed such as cabbage, lettuce and onion tops. During the winter months they ate quantities of ripe apples, as I had them turned in a large orchard and they ate apples greedily and the young turkeys were as fat as could be. What do you think about apples keeping hens from laying? In one of your articles you spoke of introducing wild blood into the stock to increase both size and hardiness. Where did you get wild stock when you raised turkeys?

Answer.—In answer to your question about yarding turkeys, I would certainly do so in the laying season, especially as you seem to have ideal yards. The apple orchard would be an ideal place for little turkeys. Apples are a very healthful food for both man and beast, and cannot hurt either chickens or turkeys. If you want to introduce some wild blood into your flock, you had better get a good young

The Great Vegetable Feed in the Best Mechanical Form for Feeding all kinds of

Stock and Poultry

Better than Bran, Shorts, Middlings or Oil Cake meal, and much cheaper.

A Pure, Unadulterated product of California Alfalfa, especially cured and treated.

The only Green Feed to be had during the entire season.

The best feed for animals intended for the show ring.

BOOKLET

Giving full particulars and instructions for feeding.

Prices for Ton and Car Lots on Application.

Calfalfa Meal

Is a superior feed for young chickens, all kinds of poultry; growing pigs, stock hogs and brood sows; sheep and lambs; young calves; dairy cows, horses and brood mares.

A pure protein feed, especially adapted to be fed to all kinds of growing stock.

Calfalfa Meal

Regulates the bowels, cools the blood, and makes bone, blood and muscle.

Enables the special organs to perform their functions.

Ask your dealer for it, or write the manufacturers for trial order.

Prices for Ton and Car Lots on Application.

Tom from Mrs. C. D. Hubbard (see her adt. in this paper); she has grand stock. It will cost you less than sending back to Arkansas and you will be well treated by her. I got my wild blood in Oklahoma. Now I am raising only a few White Holland turkeys for my own use.

* * *

Moulting.—(Mrs. J. G. C.) Will you please print in the poultry departemnt directions for "forcing the moult."

Answer.—See article in this paper.

* * *

Worms.—(L. G.) Will you kindly tell me through the Cultivator the treatment for worms in chickens? A number of my hens have had the same symptoms and finally died. They would stop eating and what was in the crop remained there. The intestinal discharges are watery and whitish. In some of these I found worms two to three inches long, resembling somewhat the earthworm.

Answer.—I think the best remedy for worms that I have tried is turpentine; thirty drops in a quart of water, shutting the hens away from all other water. Or give the hen five drops of turpentine in one teaspoonful of castor oil. The usual remedy is five grains of Santonine in a teaspoon ful of castor oil, but the turpentine does best.

Or keep the hens twenty-four hours without food and then feed them stewed garlic. If you feed plenty of onions you will not have worms. You must thoroughly disinfect your yards. Spray with five per cent solution of carbolic acid, then scatter air-slaked lime and then dig or plow and plant a crop of wheat or barley. This is to destroy the eggs of the worms. They may have been brought by pigeons or some strange fowl, and you must get rid of the eggs or you will have more trouble.

VALUE OF POULTRY MANURE.

The request has often been made to the Cultivator to give some attention to the value of poultry manure to an orchard. For instance: One party wishes to know how much fertilizer value 1,000 hens would add to ten acres. This matter has been taken up with several experimental stations and those whom we thought qualified to answer it and we find there has been a dearth of investigation along that line. For instance: we have a letter from Mr. Frank T. Shutt, from the Central Experimental Farm, Ottawa, Canada, in which he says:

"Although we have planned for some time past a series of experiments that would give us more definite information than we have at present regarding the preservation of poultry manure, press of other work has so far prevented us from taking up the investigation. There are practically no data on this subject. We know that poultry manure decomposes readily, losing nitrogen, and for this reason we have advised the use of an absorbent litter in the hen house, preferably air-dried muck, moss or peat. Ashes or lime should never be used for this purpose. We have always supposed that when such a compost is not more than one-third hen manure there is not much loss, especially if the mass is kept compact. Our proposed experiments will include the preservation of poultry manure with dry and moist loam muck, gypsum, etc., making analyses at the beginning and end to determine such losses as may ensue."

In a former letter, Mr. Shutt also said, regarding the quality and value of manure:

"In the first place, we have to recognize the important fact that the quality as well as the quantity of the manure produced will be regulated by the quality and quantity of food consumed. Speaking of the matter of quality, of which we have data, I should say that a ton of manure from poultry fed on highly carbonaceous food would not be worth more than $2.50 to $3.00 per ton, but that manure from poultry fed on a nitrogenous and phosphatic diet, such as meal, green bone and various cereal grains, should be worth from $5 to $6 per ton. In these calculations the following values have been used: Nitrogen, 15c per lb., phosphoric acid, 7c per lb., and potash, 4½c per lb.

"One authority estimates the monetary value of the manure per fowl per annum from 10c to 14c. Assuming a basis of 12c to be approximately correct, we find the fertilizing value added to the orange grove by the 1000 hens would be $120 per annum."

KEROSENE EMULSION FOR LICE.

We have several requests for reprint of the kerosene emulsion given by Mrs. Basley in last April and reprint for the benefit of those inquirers, as follows:

Dissolve one pound of hard soap, or half a pound of whale oil soap, or a heaping pint of soap powder, in a gallon of boiling water, remove from the fire and add whilst still boiling hot one gallon of kerosene. Churn or agitate briskly for fifteen or twenty minutes, or until the mixture becomes thick and creamy. Then add about ten gallons of water, cold or warm, and stir thoroughly. It should be sprayed and driven well into the cracks. I always add one pint of crude carbolic acid when I put in the kerosene.

The co-operative spirit has scarcely touched the farmer body in this country, when comparison is made with progress in Europe. In parts of the continent where co-operative societies among farmers are well organized, each particular association works along independent lines, yet the farmer is often a member of many different organizations, depending upon the particular kind of agriculture in which he is interested. An authority says it is no unusual occurrence for a Danish farmer to belong to ten local co-operative societies.

Some one has well said that there is so much bad in the best of us, and so much good in the worst of us, that it behooves each of us to be charitable with the rest of us.

We are ruined, not by what we really want, but by what we think we do; therefore never go abroad in search of your wants. If they be real wants, they will come home in search of you; for he that buys what he does not want will soon want what he cannot buy.

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

THE SILO.

(Continued from First Page.)

put in, after eight years of service, and much of the time this small silo has been filled twice a year. When the tar is properly cut with the gasoline it spreads evenly and dries quickly, and in two or three hours all odor is gone. The silo can be tarred one afternoon and filling begin next morning, without fear of having the silage taste or smell of tar.

Another reason for tarring is that the ensilage does not adhere to the sides. When the tarring has been poorly done, the ensilage sticks so closely that it is necessary to use a stiff broom or a hoe to loosen the lumps that have moulded fast to the unprotected boards. These masses weigh from one to ten pounds and are often three inches thick. If they are left clinging to the sides when the silo is filled, there will start from them a white rot that will destroy several pounds of ensilage.

The tarring of the silo is a little thing of itself, but it does not seem right to wear out things that have cost money and that means human toil.

In prosperous farming communities we often see the fixed improvements, buildings, tank-house and fences, being destroyed by carelessness. The fault of not buying new tools when needed is equally as bad, and it never pays to use mowers or wagons until they drop to pieces and are fit only for the junk heap. Sell them for what they will bring and buy new ones, and keep them in good order so the men can do a full day's work without spending the time in the discouraging labor of trying with unskilled fingers to repair breaks by tying up with baling wire.

Nearly every one coming to see our silos are ignorant of the qualities of ensilage and think it a fermented or partly decayed food, when really it is simply a canning process carried out on a large scale. The corn heats and drives out the oxygen, converting the starch into sugar, and the heavy carbonic acid gas settles down to help exclude the air. If the sides are absolutely air tight and the ensilage has been well tramped down, the temperature rises rapidly. When it reaches 150 degrees, the ferment or bacteria producing it are destroyed; and the further breaking down of the starchy matter into lactic or acetic acid is arrested. As it cools, the coating of mould appears on the surface and seals it air-tight. This makes bright, sweet silage, loved by the cows, filling the milk pail and rolling out the butter fat, bringing into the farm home many comforts, and into the lives of the children the advantages of education.

In California, complants come to us of silage failing to keep; of its being very sour; of its tainting the milk. If it fails to keep, the building is probably defective. If it is too sour, the material or food stuff was not sufficiently matured when placed in the silo and could not help developing into vinegar, just as grape juice when it has sufficient saccharine matter makes wine; but if reduced to 12 per cent of sugar and not checked by addition of alcohol, it makes vinegar.

The next common cause of failure in California is putting up the ensilage too dry. If too dry, small masses of mould will appear in places all through it. This mould does not seem to be injurious to the cattle, though it imparts a slight bitterness to the taste that they do not seem to appreciate.

If the silo has been filled too fast, the resultant heat often makes it too dry. To distribute the moisture evenly, we have a three-quarter inch faucet over the end of the carrier, and keep a small stream of water flowing constantly on the cut food as it is carried up into the silo. We never fear it becoming too wet; as the silos are on the earth without cement floors, the absorption is perfect. The moisture shows on the ground two or three feet from the silo a couple of weeks after the filling is completed.

Now about filling the silos too fast. This was our costliest mistake, for we were told by the eastern authorities, to fill at once. Our feed stuffs are drier, when brought in, than in the East, and the dry heat at Fresno is also intense; so the outside of the silo is heated to over 100 degrees where the sun strikes it directly, and the ensilage warms up with internal heat, and will scorch and turn dark. We say "scorch" for want of a better term, for there is quite a suggestion in the darkened sticky mass, of burnt molasses candy. The cows will eat this readily enough, but they do not toss their tails in the air and race to the mangers as they often do when the silage is sweet.

By filling one of the pits of the silos half full and then filling on the other pit until the former has cooled down to a temperature not too hot to hold the hand in about a foot below the surface, all danger of over heating is avoided. The pit is then filled to the top and well tramped.

It is particularly important not to over-heat alfalfa ensilage, which requires longer to cool down and more tramping to make it keep sweet, than is needed with corn. Peas and oats require the same careful handling. Corn ensilage is so easy to make perfect that it would seem only the greatest carelessness could make it spoil.

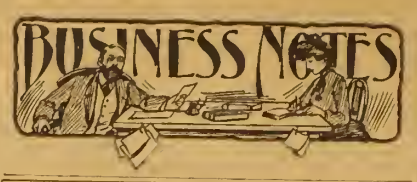
The settling of the ensilage after filling shows whether it has been well put in. Ten feet of alfalfa should not settle more than two and one-half feet; oats not more than 3 feet; barley and wheat, 3½ to 4 feet; corn about 2 feet. If the first filling settles more than this, the men tramping should be watched and made to tramp the sides more thoroughly. If the men are told the above figures before they start to tramp, they will do better work. I am more than ever convinced that we gain intelligent co-operation by letting the men understand what we are doing and why. It is more peaceful for them to discuss ranch facts at their table than to have the tea-cups and plates fly through the air during the heated disputes over religion and politics.

Ensilage like alfalfa taints the milk from the outside of the cow, not through her body. It is, therefore, better to feed it in the manger outside her milking barn. After the cows have finished all they care to eat, remove the remainder to the calf lot.

A PRACTICAL POULTRY PLANT.

A practical book for poultry people. Price $1.25 postpaid. Address this office.

Professor: "Now, Sprockets, give me some account of Atlas. Sprockets: "He was a mythological god with a bicycle stoop and the originator of the ball bearing."—Puck.



A NEW VETERINARY REMEDY.

A remedy which is known to Southern California but little, but which has been a strong favorite in many sections of the East for years, is announced in this week's Cultivator, and from testimonials which we have seen, we do not doubt is worthy of a trial by horse owners in California. It is a cough and throat medicine manufactured by the Paxton Veterinary Medicine Co., of La Porte, Indiana, but which Mr. C. C. Paxton is now in California introducing. That company manufactures not only the above mentioned remedy, but others, such as colic and indigestion cure, purgative pills, healing powders and other remedies so compounded and put up as to be exceedingly easy of administration, and with it all, an economical and everyday remedy.

By writing Mr. Paxton, at Sta. C, Los Angeles, further information may be had regarding these remedies.

MEALFALFA.

The Stockton Mealfalfa Co. are manufacturing a product made from selected alfalfa hay, prepared and ground to a meal by a special process. It is green protein food and when moistened becomes green alfalfa. The process retains all the original properties of alfalfa and makes a food very rich in protein. Best results are obtained by mixing with other grain. It is claimed to be a very superior food for poultry, hogs, horses and cattle, being nutritious and palatable, and in bulk will go twice as far as alfalfa hay. It is manufactured by the Stockton Mealfalfa Co., of Stockton, Cal., and sold generally throughout the State by dealers. A letter to the company will secure full information, circulars, sample package, and where kept in stock.

See their advertisement in this paper and mention the Cultivator in your letter to them.

STOCK APPLIANCES.

The Cultivator has often spoken of the advantage to be had from the use of sterilized air treatment for milk fever and of the further fact that while the bicycle pump treatment may accomplish good results, a more improved apparatus would probably soon be on the market which would soon make this treatment comparatively simple in the hands of any careful person. We are glad to call attention to the announcement of the Stockmen's Supply Co. at Fresno, to an appliance for treating this disease. It is said to be easy to manipulate, requires but little time, and can be used on the shortest notice. This establishment not only carries the article mentioned but general supply of stockmen's appliances and remedies.

ARID CLIMATE FIELD ROSES.

The Cultivator is in receipt of an exquisite illustrated booklet, published by the Chase Rose Co., at Riverside, and containing a large number of beautiful half tones of roses produced by the company, and a complete list with prices of the various varieties. A strong point is made on the title page in the statement, "Arid climate field-roses grow," which is probably at the foundation, at least coupled with good business management and honest goods, of the immense business which this concern has built up. As the firm caters to wholesale trade, we are not certain that this book is sent to all comers, but, if it is, it would certainly be a prize worth sending for.

A VALUABLE FOOD.

Good for horses, good for dairy animals, good for hogs, and, especially good for poultry. This is the verdict of many users of the Calfalfa meal manufactured by the California Stock Food Co., at Fresno. At this season of the year, when green food is scarce for use in the poultry yard, such food as this will be most desirable for the poultry raiser for it gives fully the advantage of the green food with comparatively slight cost. The food is alfalfa, ground to a fine powder and in such a manner that all of the food elements are available for the animal's use. It may be fed either in the mash given to poultry or to stock, or, mixed with water and kept constantly before the poultry it has proved very satisfactory. Almost every dealer in poultry or stock supplies carries this valuable food in large quantities so that it can be had in practically every section of the State.

A GOOD HATCH.

Aiken & Coe report that the monster 5,700 egg incubator brought off a magnificent hatch during the past week. The work of refilling will be commenced at once.

Mrs. Aiken says that a finer lot of healthy little chicks was never seen. The continuous and uniform heat proves most advantageous and the stronger chicks will be a strong drawing card for the big incubator.

Queries and Suggestions

BEES UNDER LIVE OAKS.

Editor Cultivator: Will you be kind enough to answer in the next Cultivator if it is a good idea to have your apiary under oak trees? Do bees gather much or any honey from oak trees? They seem to be constantly at work on and about the leaves. Are the large red ants, if not in too large numbers, considered a pest to the beekeeper?—Subscriber, Watsonville.

As a rule, it is not a good idea to have the apiary under oak or any other trees where the shade is very dense, one reason being that, owing to the shade and coolness, the working day of the bee is much shortened. To get the earliest work out of the bees in the morning, they should be out where the warmth of the morning sun strikes the hive as early as possible. We do not think the apiary would suffer any other inconvenience from being under the oak trees. It is possible that the bees gather some honey from the honey dew which is caused by aphis or other insects which inhabit the trees, but, other than that, no benefit will be found from the oak trees.

Large red ants, in small or large quantities, or any other ants, are certainly no benefit to the beekeeper. Every effort should be made to keep them absolutely from the hives. Notwithstanding this, which is usually the testimony of California beekeepers, A B C of Bee Culture says that in the North there is no injury from ants.

If you wish to kill them off, find the ant hill, drive a bar ten or twelve inches deep about the center of the hole and pour in five or ten cents worth of bisulphide of carbon. Cover the hole quickly with moist dirt and the ants will all be desetroyed.

"SCALY BARK"—GUM DISEASE.

Editor Cultivator: Can you tell me whether there is any cure for "scaly bark" on orange trees? Is is similar to gum disease?—H., Santa Ana.

We have never heard of the term "scaly bark," applied to gummosis, foot rot, mal-di-goma, or, more common, gum disease, but we presume that gum disease is referred to. It is an exasperating trouble and occurs in nearly all citrus sections of the world. There are some varied manifestations of these several diseases, but, as a rule, the same general condition prevails of decay and scaling off of the bark and a general unhealthy condition.

Be careful about letting too much dampness about the tree. Give thorough culture, allowing air to penetrate the soil. Admit air and light to the center of the tree, as much as possible. Scrape and clean off the diseased parts, scraping down to healthy wood. Disinfect by washing over with Bordeaux mixture or solution of equal parts of carbolic acid and water. After this, coat with grafting wax or any substance which will exclude air and give chance for healing.

SHYNESS OF BEARING.

Editor Cultivator: My tomatoes are troubled with some disease, or at least, I find that after blossoming the stem, half an inch or more back from the blossom, loosens from the vines and falls off. At the same time the vines are very strong, healthy growing and no appearance of disease. Why do they not bear?—Subscriber.

The trouble, we imagine, comes not from any disease whatever, but from your own fault in giving the vines too much water and perhaps too good attention. Also, another factor which may have caused it is the coolness of the season up to this time. As the weather gets hotter and drier this may be, to a certain extent, corrected and this may be aided by yourself in withholding the water and thus inducing more fruit growth and less of the vine growth. Pinch back the tips of the strongest growing branches.

THE MATILIJA POPPY.

Editor Cultivator: Please advise me under what conditions I might expect the seeds of the Matilija poppy to germinate. Also, what time is best to move and divide large clumps. Can I do it now? What are prices of plants? —C. F. S., Pasadena.

Great difference of opinion prevails among our nurserymen regarding the germination of this seed. With some it has lain in the seed tray for eight months before starting. With others the appearance of seedlings is almost immediate. More complaint and reports of unsuccessful attempts at growth, come from our own State, than from the East or Europe. We are inclined to believe that if seeds are fresh, no trouble will be found in getting a good return in a reasonable time. No poppy seed will keep well and though germinating when old, if kept too wet or cold, decay will be induced and of course, no seedlings appear. This plant seems to transplant best during February or March, just before growth starts. The next best time is after the summer growth and bloom have matured, probably about September 1st. They should be cut back heavily when moved, and well watered. If they have been kept dry previously you will be successful. We would advise placing them on the market already established in one and five-gallon cans, rather than in naked clumps. Prices are determined by size and condition of plants. Apply to any of our nurserymen.

SUB-TROPICAL FRUITS.

What is the best time to set out the sub-tropical fruits mentioned in your issue of June 2d, and what are the proper conditions, care, etc.?—F. I. P., Upland.

As all of these plants are handled in pots or cans, they may be transplanted at any time except from October to February; at that time the soil would be too cold to start them into growth and decay might start, instead. Their treatment, soil requirements, hardiness, etc., varies and you would better find out from the dealer the needs of each, or if you will state just what plants you expect to plant, we will advise you. Any plants of this class, even oranges and lemons, will do better if given protection during the first winter or winters.

SORGHUM MILL.

Some tmie ago the Cultivator received a request for information as to the making of sorghum and best and cheapest mill to use. The best information on manufacturing of sorghum syrup may be secured by writing to the U. S. Department of Agriculture, Washington, D. C., for Farmers' Bulletin No. 90. However, the success with sorghum manfacture, or rather with the selling of the manufactured article in this State, has been very indifferent. It does not seem to command a ready sale in competition with the regular sugar factory syrup. However, a few months ago, a correspondent of this paper informed us that he had been in the sorghum business for twenty-five years and had succeeded well in manufacturing and disposing of his product. He said that from rich soil he could produce three hundred gallons of syrup per acre, and at the same time could dispose of all that he could make at forty-five cents per gallon.

GRAPE TROUBLE.

Editor Cultivator:—Enclosed you will find some grape leaves. Will you kindly say what you think is the matter with the vines and what can be done for them? I have a few acres of them situated near Arrowhead. The soil is loose sand and gravel, watered in the past from hot mineral springs. Last year a portion of the vineyard was affected the same way, leaves dropping and fruit drying up. That portion is not as bad but the other portions and younger vines are badly affected this year although the growth was vigorous. The vines are three and four years old.—J. C. F., San Bernardino.

The leaves have the appearance of leaves of some varieties of grape vines when affected with the Anaheim disease. The grapes drying up on the vines is another symptom of this disease, though the fact that vines affected last year are not so badly affected this year would ordinarily be considered proof that it was not the Anaheim disease though we have seen Seedless Sultana vines have every indication of Anaheim disease one year but show no sign of any kind of trouble the following years. If the grapes begin to dry up before the leaves fall, it would indicate that the disease affects both fruit and leaves (as the Anaheim disease does), otherwise, the vines might lose their leaves from drouth or insect attacks and when the grapes were exposed to the sun they would soon dry. From appearance of the leaves and from the description of the trouble we should say that it is a mild attack of the Anaheim disease. There is no known remedy for this.

SUMMER COVER CROP.

Editor Cultivator:—I want to plant some kind of pea between corn rows for green manure and pasture after the corn is off. The land is damp and the corn is about ten inches high now. The land has been in alfalfa and has some Bermuda grass which I want to kill and if I can get a heavy mat of green stuff over the land I thought it might help.—C. W. K., El Monte.

The common vetch will make a heavy growth and produce good feed. The cow pea will do the same if sown this time of year. It will outgrow the vetch and make excellent hog feed when the beans are in the dough. The vetch has the advantage over the cow pea in that it will make good late green feed even through the winter. The cow pea will mature and dry up before fall.

BOOK WANTED.

Editor Cultivator: Can you inform me the publisher's name of "Young's Secrets?" This is a book that should be in every rancher's, mechnic's and poultryman's hands. The one I saw was an old volume from which the publisher's name was torn.

I would like the points of perfection in Rhode Island Reds. It is not given in the Standard with other breeds.—W. F. W., Redlands.

Regarding the first query, we have been to Los Angeles Public Library and to many of the largest bookstores and are unable to locate "Young's Secrets," though the book dealers have gone through, most thoroughly, complete catalogues of publications for many years. Any subscriber of the Cultivator who can give the desired information will confer a favor.

The new Standard will contain the scale of points of the Reds. This will be out in a short time. "The Poultry Book," published by Doubleday, Page & Co., three volumes, $12, can be supplied from this office and this contains not only a scale of points, but a complete history of the breed. The book may be had in all three volumes or the one volume containing history and standard of the Rhode Island Reds for $4.

We note the suggestion in a southern paper regarding treatment of spring crop of potatoes to ripen the seed for the fall planting. It is, after the potatoes are thoroughly ripened in the ground, to dig, cut the potatoes and, after drying over slightly, store in a long furrow, making a sort of winrow after which dirt is plowed over them. They are left thus covered until beginning to sprout, when it is easily determined which are thoroughly ripe and ready for planting by their being sprouted.

The Florida melon season closed about July 1st and is said to have been an exceedingly successful season, with large output. The output of the southern end of the State is about one thousand carloads.

In nearly all cases it is better to apply the manure thick than to attempt to make it go as far as possible by spreading it on in thin layers.

When putting down carpets, stretch them lenghtwise. Tack down the two ends first, i. e., across the ends of the breadths. After it is straight and stretched, the sides are easily tacked and do not require as many tacks as the ends.—Farmers' Tribune.

RANCHES WANTED
Want five improved and three unimproved Ranches in Southern California for cash. Price from $3,000 to $25,000. Perfect titles. Give full description and price. Will deal with owners only.

HIS NEW BROTHER.

Say I've got a little brother,
Never teased to have him, nuther,
But he's here.
They just went ahead and bought him,
And last week the doctor brought him,
Wasn't that queer?

When I heard the news from Molly,
Why I thought at first 'twas jolly,
'Cause, you see
I s'posed I could go and get him
And then mamma course, would let him
Play with me.

But when I had once looked at him,
"Why," I says, "My sakes, is that him
Just that mite!
They said "Yes," and "Ain't he cunnin'?"
And I thought they must be funnin'—
He's a sight!

He's so small, it's just amazin',
He's so red;
And his nose is like a berry,
And he's bald as Uncle Jerry,
On his head.
Why, he isn't worth a dollar;
All he does is cry and holler
More and more;
Won't sit up, you can't arrange him—
I don't see why pa don't change him.
At the store.

Now we've got to dress and feed him,
And we really didn't need him
More'n a frog!
Why'd they buy a baby brother
When they know I'd good deal ruther
Have a dog?

—Joe Lincoln.

Mistress Ashe's Punch Bowl

(A Historic Incident of the American Revolution.)

Wild roses in North Carolina are red. In the earliest days there were fields of these roses, bright and glowing, to be seen from the doorstep of the hip-roofed house of the Ashes.

On a summer morning in 1781 Mistress Ashe stood on the threshold of her home and, sheltering her eyes with slim fingers, she gazed intently Newbern way. In the dusk of the great hall behind Mistress Ashe showed a crowd of dark frightened faces, the slaves had crowded to the mansion at the first report of the coming of the British foe. Except for these slaves Mistress Ashe and her sister were alone. The sister was that Mistress Wiley Jones, stories of whose charm of manner still bloom perennial in North Carolina history and song. Mistress Jones was now on a visit from her own home in Virginia.

The column of dust rapidly approached. The sound of marching feet might almost have been heard.

Mistress Ashe turned to one of her slaves: "Go quickly," she commanded. "Request my sister to come hither with all haste to tell me what cheer she offered this Tarleton, whom I fear brings now on us his host"—

The slave had scarce disappeared when Mistress Jones, just learning of the dreaded approach of the enemy, was hastening to her sister.

"Is it, indeed, Tarleton?" cried Mistress Jones. "Is it, indeed, that bragging colonel? I must tell you, sister, that this same Tarleton bears me a grude"——

"Heaven forbid!" exclaimed Mistress Ashe, for Tarleton's wrath was to be dreaded.

"When the English under Cornwallis marched from Wilmington to Virginia," pursued Mistress Jones excitedly, "while they tarried upon the Roanoke, a party of officers were quartered upon us. Among them was this Tarleton. On the night on which they were to leave us this braggart grew very bold in his talk of us 'of the rebellion,' as he called us. Roundly he abused our noble friend, Gen. George Washington; more rudely still our dear friend and the General's kinsman, Col. William Washington. He spoke of him as 'that illiterate fellow.'"

"What!" cried Mistress Ashe.

"True. And moreover," quoth Mistress Jones, "he said: 'I hear this much vaunted fellow—this Will Washington—can scarce write his own name."

"Ah," quoth Mistress Ashe, indignantly.

"Then, ere pausing for prudent thonght, I cried: "But, Colonel Tarleton, you ought to know better than that, for you bear on your person proof that he well knows how to make his mark!"

"My sister!" cried Mistress Ashe, "dared you so allude to that saber stroke in the hand which the gallant Washington did give this Tarleton at Cowpens!"

"I had cause to regret the swiftness of my tongue," declared Mistress Jones, "for he straightway put his mark of devastation on the sundry parts of my property."

"Stay!" cried Mistress Ashe, with a startled gesture of remembrance. "Hast thou heard of the three-fold oath that this Tarleton has registered, repeating it till its braggart echoes resound from seaboard to untouched forest?"

"Tell me in all haste," urged Mistress Jones, "for they are now almost at earshot."

"He has sworn that he will plant the flag of old England on every housetop in our land—if not on turret, then, forsooth, on the ashes of every dwelling. He hath sworn that he will carry our noble leaders, the Washingtons, in chains to England. He hath sworn that he will quaff a stirrup cup, a luck drink to these horrid accomplishments, from the Ashe punch bowl!"

"Heaven defend us!" ejaculated Mistress Jones.

On the instant the two beautiful sisters presented an undaunted front to the foes.

General Leslie was in command, and right glad were the sisters that the hot-headed Tarleton was accompanied by a superior officer. Right graciously did General Lelie request what he might have demanded from the defenseless women, food and drink for his men and his officers.

The shining mahogany was soon set out with ample store. The Saracen's head peering from the heraldic device on every glittering piece of silver

seemed to desire now to exchange its noble motto, "Non sibi sed alenis," to a ringing "A strong arm for us and a sword-point for others."

But the Saracen heads kept all to their inviolable silence. Mistress Ashe also held her lips through all Tarleton's braggart abuse of the forces of her countrymen, while her heart beat with anxiety lest he take this occasion to demand a brew in the Ashe punch bowl.

Minded of the thrust in the parrying of wits with Mistress Jones had dealt him on the Roanoke, he was fain now to repeat his bit of braggadocio, sure that Mistress Jones would now be at his mercy, fearing, as she surely would fear, to bring by any bit of her tongue's sharpness his anger upon her sister.

"Here, too, Mistress Jones," he cried loudly, "I find friends of those ungainly woodsmen, the Washingtons. Would I could see these wonders of the Western world, these"——

"Ah, Colonel Tarleton," rang out Mistress Ashe's clear tones, "had you but looked behind you at Cowpens, when you fled so unceremoniously, you could have had that pleasure."

On the instant Tarleton grasped his sword hilt. Bitterly did Mistress Ashe repent on the instant of the piece of repartee, since become a line in our history.

What would have been the instant result of Tarleton's wrath none could tell, for at that moment General Leslie, hitherto detained without, entered.

Quickly he inquired the cause of Mistress Ashe's agitation; quickly on learning the cause he rebuked the colonel: "Say what you please, Mistress Ashe. Colonel Tarleton knows better than to insult a lady in my presence."

The colonel, greatly chagrined at this rebuke in the face of his subalterns, laid a plan for speedy revenge.

He well knew that Mistress Ashe would be daring enough to refuse from himself a demand for a draught from the famous brew, to be tasted only at Ashe house, but he fancied that she could not now refuse a request from his general, since that courtly gentleman had so readily taken her part against himself.

With no hint of his oath, Tarleton led the talk to the noted Ashe punch bowl. He related for his general's hearing the many stories of that bowl, antique in England ere the Mayflower's keel had cut the ocean plying westward. He told how in America it had grown thrice precious to its owners, for that almost every American leader of the Revolution had sipped exhilarating draughts from its generous crystal depths. He told how about this very board there gathered around that bowl, when chance and change of war permitted, five officers of the Revolutionary army, all of one name and blood; Gen. John Ashe, his son, Capt. Samuel Ashe, Col. John Baptista Ashe, Samuel Ashe, later to be the first governor of North Carolina chosen by the people, and Cincinnatus Ashe, a captain of marines, and besides these five officers there was another, a private, being too young to hold a commission, but not too young to give his life to his country.

"Mistress Ashe," cried Leslie, "the soldier of any nation may feel honored to taste a draught from a brew that so many brave men have quaffed. Now since you have so amply entertained your foemen, can you not add to your hospitality, I pray you, a draught from the Ashe punch bowl?"

Triumph at the success of his ruse shone on the ruddy countenance of Tarleton.

Mistress Ashe ordered the brew to be brought. After the delay necessary to the concocting of so rich a beverage the bowl was borne into the dining hall.

The crimson sides of the bowl caught the summer sunshine and glowed with deeper rudescence. Fragrance of roses, spices, wines, filled the hall. On top of the softly surging, wine-rich waves floated a million rose petals—wild rose peals—shredded from golden centers.

Mistress Jones, intrepid woman that she was, trembled where she stood. She felt that if Tarleton must now quaff a luck drink to his declared designs from that bowl, destruction awaited her countrymen and its leaders.

Mistress Ashe rose from her seat at the head of the table. General Leslie and his officers rose with her.

"General Leslie," spoke Mistress Ashe, "this bowl is the most precious possession of my husband's people. Generation after generation have sipped the nectar of this brew therefrom. The men who have tasted of this fragrancy have ever been of the brave the bravest, yet they were gentle as women to the weak and the defenseless. To such a one, General Leslie, be he friend or foe, I will offer a draught from this bowl."

Whereupon she poured a glass for General Leslie. While the General held his glass uplifted, waiting the filling of all the glasses, Mistress Ashe turned to address Tarleton.

"Colonel Tarleton," she said, "I have heard of your triply strung oath. I have heard that you have sworn to plant the flag of England on the roof of every American home, or, failing that, on its ashes. I have heard that you have sworn to carry our leaders in chains to the foot of the throne."

The Colonel's face glowed with fierce anger.

"And I have heard," pursued Mistress Ashe, "that you vowed to take your stirrup cup ere you ride forth on the accomplishment of these intents, from the Ashe punch bowl"——

There was a moment's tense silence, when Mistress Ashe spoke again:

"Heaven grant that our leaders in war may become our rulers in peace!" Mistress Ashe put her slender hands about the bowl and lifted it high above her head.

"Colonel Tarleton!" she cried dauntlessly, "as now snaps one cord of your triply strung oath, so may all arrows shiver from the slacked bow of the braggart! For never, Colonel Tarleton, from the Ashe punch bowl shall cup be offered to the cruel foeman of our people!"

So saying she let slip the precious burden from her uplifted hands.

Drenched with the ruddy dew, her hair crowned with the rose wreath that had fallen from the bowl as she cast it from her, ith red rose petals fluttering from erect shoulders to high arched feet, she made a picture beautiful, dauntless.

General Leslie dropped his glass untouched on the crimson wreck that had splashed its brilliancy over the waxed floor of the hall.

Outside in the brilliant sun of July a million rosebuds grew for fresh blooming, but never more would any of their kind crown rich libations in the once priceless, now shattered, punch bowl of the Ashes of North Carolina.—Springfield Republican.

Cookery Recipes

RECIPES.

Fish Croquettes.—To one cup of cold, cooked, flaked fish, add half a cup thick, white sauce. Season with salt and pepper and stir over the fire until boiling. When done spread on a platter to cool and divide into as many portions as are needed. Shape, roll in bread crumbs and fry in smoking fat a nice brown. Serve with lemon slices.

Welsh Rarebit.—Melt one tablespoon of butter, add a teaspoon of cornstarch and stir until well mixed. Then add half a cup of thin cream and cook two minutes. Cut in fine pieces half a pound of mild cheese and add to it the mixture with a teaspoon each of salt, mustard and a few grains of cayenne. Stir until soft and creamy. Serve on toast.

* * *

Potatoes au Gratin.—Slice four cold boiled potatoes. Melt two tablespoons of butter in a frying pan, add two tablespoons of flour and stir until smooth. Then add one cup of thin cream and one cup of stock. When boiling remove from the fire and add the yolks of two eggs and three tablespoons of grated cheese, salt and cayenne to season. Put a layer of sauce in a baking dish, then a layer of sliced potatoes, then more sauce, and continue until the dish is full. Spread over the top butter bread crumbs and brown in a hot oven.

* * *

Delicious Baked Fish.—The following receipt is applicable either to cod or haddock. Select a fish weighing three pounds and remove the skin and central bone. Break two eggs into a bowl and beat well with one pint of milk. Then add three snowflake crackers broken into tiny pieces; also one teaspoon of sugar, one-quarter teaspoon of salt, a dash of pepper and a grating of nutmeg. Butter a baking pan, lay in one piece of the fish, sprinkle with salt and pepper and pour half of the cracker and egg mixture over the fish. Cover with the second piece of fish, season and add the remaining sauce. Cook in a slow oven, and as custard forms in the pan lift it carefully from the sides of the dish and place on top of the fish. Repeat the process every ten minutes. When the fish is nearly coked, cover the top with small bits of butter and allow it to brown. Arrange on a hot platter, garnish with parsley and sliced lemon and serve with Hollandaise sauce.

Rice a l'Italienne.—For five persons one pound of rice will be required. Wash thoroughly in several cold waters, then dry and cook in a large kettle two-thirds full of boiling water until it is soft enough to be easily broken, but not soft enough to mash. Drain thoroughly and cool. Put one-fourth pound of butter in a saucepan with one medium sized onion, shredded. Cook slowly until well browned, then add the rice and quarter pound of grated cheese. Mix with two forks until well blended (never stir rice with a spoon). Cover the pan tightly and cook in a moderate oven for twenty minutes.

* * *

A Novel Potato Salad.—This salad, combines potatoes with nuts, and is hearty enough to make the main dish for the family luncheon. For four potatoes allow one cup of English walnut meats, a slice of onion, a bay leaf and a blade of mace. Add the seasoning to boiling water with a little salt and cook the nuts for ten minutes. Drain and throw into ice water until thoroughly cold, then dry in a soft towel. Add to the potatoes, which should be boiled until tender, sliced and kept hot until blended with the dressing. For this place one-quarter teaspoon of salt and half that quantity of white pepper in a bowl with three tablespoons of olive oil. Add one tablespoon of vinegar measured in a spoon which has

been rubbed with a clove or garlic. Cut the onion into bits, mix it with the hot potatoes and cold nuts and blend with the dressing, which has been stirred until thoroughly mixed. Stand on ice and serve on a bed of lettuce leaves.

The weather and crop conditions for the week ending July 17 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—Clear weather prevailed throughout the State during the week, with frequent light fogs in the coast districts and a light local shower in the vicinity of San Diego. The extreme heat of the preceding week was followed by much lower temperature in all section, continuing up to the present.

(Note:—The maximum temperature at San Diego last week was incorrectly reported as 86 degrees instead of 74 degrees.)

Grain harvesting and threshing and hay baling are progressing rapidly. Grain is far below early estimates in the Sacramento and San Joaquin valleys, but there is a fair crop in the coast districts and an excellent crop in Southern California. Hay has yielded the best crop for several years. Sugar beets are yielding well and are of excellent quality. Hops and beans are in good condition and making rapid growth. The heat of last week caused but trifling damage to beans and sugar beets. Corn, potatoes and vegetables are doing well. Feed is still plentiful and stock are in good condition.

Grapes and deciduous fruits were considerably injured by the heat of the preceding week, but the cool weather following has had a very beneficial effect and the loss will not be as great as anticipated. Fruit harvesting is progressing and heavy shipments are being made. Grapes are rapidly maturing and give indications of a large yield. Citrus fruits, nuts and olives are in excellent condition in most sections.

Eureka Summary.—In many places hay is mostly cut. Grass in interior and high altitudes is turning brown and rain would do more harm than good, but crops generally need moisture.

Los Angeles Summary.—Fruit is drying slowly in the coast sections on account of cool, cloudy weather. Oranges and lemons are making vigorous growth and promise good crops. Wild feed is plentiful on ranges. Stock is fat and in good condition. The honey yield is very good.

The State Board of Equalization began its summer session at the State Capital this week. It is expected that the tax rate to be levied for next year will be under fifty cents. The last rate was fifty-three and a half cents, but the increase in valuation this year promises to be over $100,000,000.

Supervising Engineer J. B. Lippincott of the U. S. Reclamation Service, announces that the contract for the Yuma dam has been awarded, the contract price being $900,000. This project involves the reclamation of lands lying in both California and Arizona, near Yuma on the Colorado river. The Klamath project, lying partly in California and partly in Oregon, will probably be under construtcion soon.

Los Angeles Markets.

Los Angeles, July 19, 1905.

Butter.

Butter quotations the same as last week, though it is predicted an upward tendency is observable. Supplies have already been drawn from storage to fill orders and shipping orders are largely increasing. Some butter dealers claim that butter was shipped in more directions from this market on Monday than was ever done before. Good shipping orders came from Los Vegas, New Mexico, and from almost every surrounding town.

DRIED FRUIT.

Dried fruit market is of little interest, there being quite a wide range between the producers' ideas and those of the buyers. Producers are holding for as close to six cents as they can get, while the buyers are insisting that the market will not stand over five cents. The holdover crop is practically one-fourth of that of last year. Then general tone of the prune market is much stronger and there is less distance between the buyers and sellers on the coming crop.

San Francisco, July 19, 1905.

DAIRY.

Scarcity of fancy butter has given the market a decidedly firmer tone and all grades have advanced correspondingly. The increased price has turned many buyers from fancy to choice grades. Prices are materially higher than last week and nearly all stock is quickly picked up at top quotations.

BUTTER—Per lb:

Creamery, fancy	23 @23½
Creamery, good to choice	21 22
Dairy, choice	19 @20
Store	16 @17

CHEESE—Per lb:

Cal. Creamery, mild new, ex.	11
Do, choice	9 @10
Young American	12 @13
Eastern, N. Y., Cream	17 @18

EGGS.

Eggs have been materially advanced though common stock is very plentiful. Owing to the continued hot weather, the lower grade stock predominates and in these grades it is hard to get the maximum prices.

EGGS—Per doz:

Ranch, selected large	25 @26
Ranch, good to fancy	22½@24
Store	17 @20
Eastern, firsts	18 @19
Eastern, seconds	16 @17

POULTRY.

Receipts of poultry from local sources have been very heavy the last few days, mostly young stock, and market is materially easier than for some time.

POULTRY—Old Roosters, per doz., $4@5; young Roosters, $5@6.50; Fryers, $3.50@4.50; Broilers, $2@3; Hens, small, $4@5; large, $5.50@6.50; Live Turkeys, per lb., 19@21c; Spring Turkeys, 24@28c; Ducks, old, $4@4.50; young, $4@4.50; Geese, per pair, $1.25@1.50; Goslings, $1.50@1.75; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $1.50@1.75.

FRESH FRUITS.

Peaches, apricots and plums have come in in very large quantities within the last few days, part of the time the market in these commodities being entirely off, though real fancy stock has, as a rule, commanded quick sale. Canneries have absorbed a large quantity of the offerings of lower grade stuff at from $15 to $25 per ton. Grapes are coming in plentifully and prices have been affected by the quantity. Fresno watermelons are coming in and, being of exceptionally high quality, sold as high as $3.50 per dozen.

Apples—Per box, fancy, $1@1.35; common to choice, 40@75c.

Apricots—Per box or crate, 25@50c; bulk, per ton, $8@20.

Figs—Per large box, $1.25@2.25; small box, 75c@$1.

Pears—Per box, Bartlett, No. 1, $1.50@1.75; common, 50@75c; other varieties, 50c@$1.25.

Peaches—Per box, 25@50c; basket, 40@50c; large boxes, 50@85c.

Plums and Prunes—Per small box or crate, 35@75c, as to variety; bulk, per ton, $10@15.

Nectarines—Per crate, White, 50c; Red, 50@75c.

Grapes—Per crate, 75c@$1.50.

Cantaloupes—Per crate, Coachella, $1@1.75; San Joaquin, $1@1.75; River, $2.50@4; Watermelons, per lb., 1½c; per doz., $1.50@3; Nutmeg Melons, $1@$1.50.

Blackberries—Per chest, $1.50@3.

Currants—Per chest, $5@6.

Loganberries—Per chest, $4@5.

Raspberries—Per chest, $3@5.

Strawberries—Per chest, Longworths, $2@4; large varieties, $2@3.50; Santa Clara Berries, $3@4.

Huckleberries—Per lb., 12½c.

VEGETABLES.

Vegetable market is without special feature. Potatoes are plentiful and coming in in better quality. Several Australian offerings have been absorbed at top quotations. Tomatoes have increased vastly in offerings, hence have sharply declined.

VEGETABLES—Tomatoes, small box or crate, 20@30c; large box, 40@60c; Green Peppers, per box, 75c@$1.25; Dried Peppers, Southern, per lb., 10@12c; Stockton, 11@12c; Okra, per box, $1@1.25; Beans, per lb, Green, 1@2c; do, Wax, 1@2c; do, Lima, 3@4c; Garden Peas, per lb., 3c; Cucumbers, per box, 60c@$1; Summer Squash, per box, 65c@$1; Egg Plant, per box, $1@1.50; Garlic, per lb., 3@4c; Green Corn, per sk, 50c@$1; per crate, $1@1.75.

ONIONS—Per sk, Red, nominal, Yellow, $1.15@1.35.

POTATOES—Per ctl: River Burbanks, in boxes, 85c@$1.15; in sks, 50@75c; Salinas Burbanks, 85c@$1.15; Early Rose, 50@60c; Garnet Chile, 50@60c.

DRIED FRUITS.

The dried fruit market is becoming much more active and on prunes the growers demand for a 3-cent basis has been conceded, and now some growers are not anxious to close out too quickly. Fine peaches are nearly all going to canners, which is causing a scarcity of the highest drying stock.

Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb. as follows:

Apples—Evaporated, 1905 crop, choice, 6½@7c; Sun Dried, nominal.

Peaches, 1905 crop—Crawford, fancy, 7@7½; choice, 6@6½; standard, 5½@5¾c; Muirs, fancy, 7½@8c; choice, 6¼@7c; standard, 6c.

Plums—1904 crop, Pitted, 6@8½c, as to quality.

Prunes, 1904 crop—Sack basis, f. o. b.: For boxed goods add ¼@½c; 30s to 40s, 5½@6½c; 40s to 50s, 4@4¼c, 50s to 60s, 2⅞c; 60s to 70s, 2⅜c; 70s to 80s, 2@2¼c; 80s to 90s, 1⅞c; 90s to 100s, 1¾c; 100s to 120s, 1½c; 1905 crop, 3@3¼c basis for Santa Clara four sizes, other sections ¼c less.

Apricots, 1905 crop—Royal, fancy, 7¼@7½; choice, 5¾@6½; standard, 5¼@5½; Moorpark, nominal.

HONEY AND BEESWAX.

Honey is in heavy receipt with comparatively limited demand, which has greatly reduced former quotations.

BEESWAX—Per lb, 28@29c.

HOPS.

The price of desirable stock is nominal at 24@27½c per lb, according to quality, many producers demanding thirty cents.

LIVE STOCK.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@5½c; rough heavy, 4¼@4½c; common, 3½@4c.

HAY AND FEEDSTUFFS.

HAY—Per ton: Wheat, $8@13.50; Wheat and Oat, $8@12; Oat, $7@11; Barley, $6@9; Clover, $7@10; Alfalfa, $6@10; Stock, $5.50@7.50.

FEED CORN MEAL—Choice Grades per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $22.50@23.50.

COCOANUT CAKE—In lots of 10 tons, $22; 5 tons, $22.50; less quantity, $23. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $25.50@28.50.

FLOUR AND CEREALS.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 shipping, per ctl, $1.47½@1.52½; White Milling, good to choice, $1.55@1.65.

OATS—Good to choice, White, nominal; Red, $1.22½@1.30 for new crop.

BARLEY—Choice No. 1 Feed, $1@1.05; off grades, 96¼@98¾c; Shipping and Brewing, nominal.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.45@1.47½; small do, $1.50@1.55; White, $1.37½@1.42½; Eastern, Yellow, $1.37½@1.42½; White, $1.37½@1.42½; mixed, $1.35@1.40.

RYE—Good to choice, per ctl., nominal; new, $1.45@1.50.

CITRUS MARKETS

The Valencia market has remained about the same during the past week, with auction markets not quite equal to prices at which the West are taking them, where the demand is more active and everything in sight is being used at full prices for desirable sizes. Fancy fruit is brining $3 to $3.15, f. o. b., with extra choice $2.85 to $3, and choice at $2.75 to $2.85. Rather light shipments are going out, mostly on order.

* * *

The Lemon market, on account of the hot weather, has gone skyward. California Lemons are selling at $4.50 to $5.50 per box in western markets and about the same in auction markets where the fruit arrives in fair condition. With the stocks on hand in California run down to fresh cut fruit, there is little likelihood of prices being low in the immediate future, although such extreme prices can only be expected under weather conditions that make heavy consumption.

NEW YORK.

The orange market was very quiet during last week, lower grade stuff being a drug on the market and closing, if anything, weaker than the opening. Navels were entirely off, both in quality and price, often being but little more than transportation charges. Sweets and Mikes sold fairly well, and Valencia Lates commanded good prices all through. Weather was intensely hot and depressing to all business.

Lemons sold at very high prices, the weather proving a stimulus to the market. Store prices ran from $5 to $7 and held on good stock at those prices.

* * *

Sixteen cars sold at Mondays auction.

Some quotations were: Valencias.—Old Mission, fy, Chapman's, $4.90; Cloister, xf, Rubidoux Co., $3.95; Blue Seal, xf, A. C. G. Ex, $3.85; Niagara, xf, Stewart F Co., $3.10.

Sweets averaged $2.40 and lemons averaged $3.95 to $4.50. 12,000 boxes of Sicily lemons sold.

Tuesday's intensely hot weather reduced the demand for oranges and correspondingly increased the demand for lemons, oranges arriving in a very bad condition, some so much so that they did not bring transportation. Lemons were exceedingly strong, ranging from $5.50 to even $7.00. Thirteen cars sold.

Valencias commanded good prices, fancy prices being around the $4.00 mark and choice at $3.00 to $3.50. The demand for sweets light. Prices averaged $2.00 to $2.50. Lemons continue active, very ordinary stock going at $3.60 to $4.00, better grades between $5.00 and $6.00. 17,000 boxes of Sicily lemons sold during the day.

Six cars of oranges were sold in the auction on Wednesday. Old Mission Valencias topped the market at $6.20. Outside of Valencias the prices were exceedingly low. Intensely hot weather is seriously affecting the market for oranges and having quite the reverse effect on lemons. A dispatch says that one car of machine-wrapped Valencias of Gypsy Queen brand was sold at fine prices. One reason for the low prices usually prevailing with oranges is made that in the humid atmosphere stock melted away and decayed almost as soon as removed from cold storage.

Average prices received were in Valencias: Old Mission, fy, $5.15; Gypsy Queen, fy, Riverside, $4.30; Golden Flower, xf, R G O, Redlands, $4.30; Golden Harvest, xf, Rubidoux, Riverside, $1.65.

Lemons, Red Ribbon, fy, $4.15; Fox, xc, Upland, $3.12; Pico, xc, S-T Ex, Whittier, $2.60; Bonnie, xc, S-T F Ex, Arroyo, $3.10.

BOSTON.

Nine cars sold at Monday's auction, all oranges except Valencias commanding very low prices.

Some quotations were: Valencias.—Quail, xc, O-C Ex, $4.05; Mocker, O R, Spence Ft Co., $3.65.

Sweets averaged $2.50, some extra fancy Mikes selling at $5.70. Lemons sold at $4.50 to $6.00.

Six cars sold at Tuesday's auction. Market steady. Weather exceedingly hot. Valencias strong, choice grades bringing $3.35 to $3.60, and strictly fancy selling at about $4.05. Market exceedingly active on lemons, choice grades bringing $4.00 to $5.50.

PHILADELPHIA.

Ten cars sold on Monday, Valencias selling around the $3.50 and $4.00 mark, sweets barely covering freight and packing. Some grapefruit sold as low as .45. Lemons firm at $3.00 to $4.00.

* * *

Total number of shipments of fruit since November 1st are 27,747, of which 3295 were lemons.

Law is like prussic acid—a dangerous remedy, and the smallest dose is generally sufficient.

The sins of ignorance are most numerous, but the sins of knowledge are most dangerous.

ORPHANS RECEIVED.

The following children have been received in the Boys' and Girls' Aid Society Home since last published notice:

1. Ray James, half orphan, age 12, eyes grey, hair brown. 2. Lillie Hastings, half orphan, age 11, eyes blue, hair brown. 3. Helden Hastings, half orphan, age 7, eyes blue, hair brown. 4. Mary Hewitt, orphan, age 9, eyes blue, hair brown. 5. Wm. Mendoza, half orphan, age 6, eyes black, hair black. 6. Josie Rivera, half orphan, eyes black, hair black, age 6. 7. Rena Huddleston, half orphan, age 7, eyes blue, hair brown. 8. Sena Huddleston, half orphan, age 7, blonde. 9. John Huddleston, half orphan, age 11, eyes hazel, hair brown. 10. James Gibbs, half orphan, age 9, eyes blue, hair brown. 11. Cecil Gibbs, half orphan, age 9, eyes blue, hair brown. 12. Winifred Nichols, half orphan, age 6, eyes blue, hair brown. 13. Max Nichols, half orphan, age 5, eyes blue, hair brown. 14. Chester McCawley, half orphan, age 9, eyes brown, hair brown. 15. Stella Watts, half orphan, age 8, eyes grey, hair brown. 16. Edward O'Leary, half orphan, age 2, eyes blue, hair brown. 17. Myrl O'Leary, age 4, half orphan, eyes blue, hair brown. 18. Walter Fowler, half orphan, grey eyes, light hair, age 8. 19. Edna Hulbert, orphan, age 10, hazel eyes, brown hair. 20. Marjorie Duff, half orphan, age 9, eyes blue, hair light brown. 21. Harold Duff, half orphan, age 9, eyes blue, hair brown. 22. Maggie Clements, orphan, age 6, colored. 23. Lucy Clements, orphan, age 9, colored. 24. Howard Clements, orphan, age 13, colored. 25. Carmilita Taliberti, orphan, age 11, eyes black, hair black. 26. John Taliberti, orphan, age 7, eyes black, hair black. 27. Louis Taliberti, orphan, age 10, eyes black, hair black.

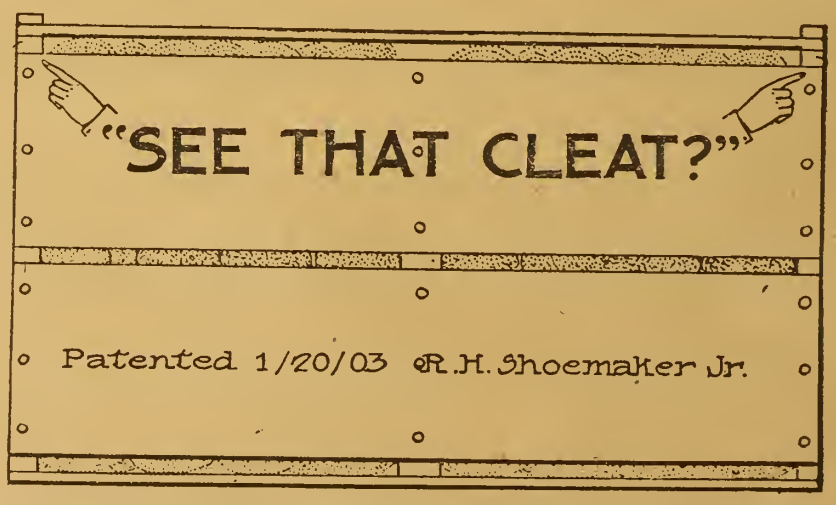
How Will You Ship Citrus Fruits Next Year

What will you do with your Oranges? What will you do with your Lemons? How is it possible to get the most money out of them? The quickest, the surest, with least perplexity?

Let's talk it over quietly for I believe I can place your entire output for cash. I have had seven years experience as resident salesman for the largest California shippers in New York, Chicago, Kansas City, Pittsburg, Cleveland, Minneapolis, St. Paul and surrounding towns, and twelve years buying and shipping in California. Both Eastern experience and experience in California justifies me in saying that I can get the best money out of your fruit. But better than all, is what I have done.

I Have Marketed Over 500 Cars This Year

and nearly three months yet to ship, and successfully and to satisfaction of the producer. I can place your fruit for cash. My trade is of the best because of the fact of knowledge of the business and because of my use of my ***Patent Cleat*** on end of box underneath the cover.



Those oranges look nice there, don't they? All even; No Compressing; No Bruising of the fruit—yet the Boxes are Full Pack.

Why do you handle oranges and lemons like eggs until you nail on the lids, and then soak it to 'em.

Can you give me a reasonable answer? No? Just habit? Well, then you are simply in a rut and blind to your own interests and not up to date. And yet you know or feel it's wrong to compress them.

This cleat has proven a wonderful fruit saver. Fruit shipped under it shows less than a half of the decay of that shipped under the great pressure of the ordinary box. My package helps sell your fruit.

It's a winner. Associations should confer with me at once regarding handling next year's crop. It may help you to an early decision and it may mean to you a greatly increased return.

How May the Thrips be Controlled?

An Interesting Article on Life History and Observations as to Control of the Pest of Prune Orchards, by Dudley Moulton, Entomologist of Santa Clara County.

The editor of the California Cultivator has several times asked for our experience with thrips here in the Santa Clara valley, and each time we have hesitated, feeling that we did not have enough definite data to warrant an article, but now that the insects have concealed themselves in the earth, awaiting another season of opening buds and blossoms, February, 1906, it seems an opportune time to give to the readers of the Cultivator and others, what we have learned during the year, and, based on this, if we may, offer a suggestion as to a possible means of control.

As is now known, this thrips is a pest in other parts of California, and has been for several years though the nature of injury by it has not been explained nor has anything been done to keep the insect from spreading or to check its ravages. Therefore, we feel that the work done here will prove of value to all who are interested in this subject of thrips and especially to those who are seeking a remedy. There has been much over-anxiety during the past year because of the great lack of knowledge of this particular insect, no one seeming to know how many broods there were to be, where the insect came from, when it arrived on the tree, or where it went to when it left; we hope this will in a small way fill this vacancy and alleviate this anxiety for the coming year.

* * *

Species.—Three species of thrips have come prominently to our notice, Euthrips pyri, the pear thrips, or the thrips which has concerned us most, Euthrips tritici, the grass thrips found commonly all the year round in roses and other flowers and blossoms, and which is often taken for the pear thrips, and Thrips tabaci, the onion thrips. The last named has been very abundant in onion fields and is common in many of our wild flowers, and of late has been found feeding in terminal buds on branches of our fruit trees. That habit is similar to that of the pear thrips and has occasioned this, the onion thrips, to be taken for the other. The grass and onion thrips have several broods or rather have a continual breeding season, and can be found in almost any stage at any time. The pear thrips is distinctly a winter form, there is but a single brood a year and though similar in external appearances its habits are decidedly different from those of the others.

* * *

First Observed.—The injury of thrips in our fruit trees came prominently to the attention of orchardists in February, 1904, when men noticed that their trees were not coming into blossom in their natural way, buds appeared blasted, turned brown and fell without opening, trees which did bloom dropped their blossoms early and in either case trees looked much as though they had been scorched by fire. This browning and dropping off had happened in places for several years but was not explained until February, 1904, when it was definitely determined to be the work of an insect, a thrips. It was also learned that these insects could completely clean an orchard of its fruit and this year wherever thrips appeared, though few in numbers, people naturally expected the worst.

Prune Branches, on Which All Blossoms Have Been Injured, and Many Have Completely Fallen from the Buds.

Life History and Habits.—In brief, the life-history and habits of this insect are as follows: Full grown adult thrips come to the trees in February, when new buds and blossoms are just opening out, they at once begin to feed and later to deposit eggs. The insect makes up for her (for all insects which come to the trees are females) long fast by ravenous feeding and this is easily appreciated by the great amount of injury which a few insects can effect and the dispatch with which they can do it. With regard to the feeding of adult thrips, suffice it to say that they attack all newly exposed leaf or blossom tissue on any of our fruit trees, some of the walnuts, also grape vines. If possible they force their way down into the bud and feed where they are wholly or partly concealed. They work in one place or on one tree for awhile, then move to another and even still others as they find better food. They leave their feeding places at evening and hover about the tree or fly or are carried on a breeze to other places, thus the insects are easily spread from tree to tree and orchard to orchard.

For depositing eggs preference is given to newly exposed leaf petioles or blossom stalks, later to the midrib and veins on the back of the leaf, or to the tissue of the leaf itself. The epidermal layer is first broken or torn away by the mouth, then the insect, moving forward a little, cuts an incision with her saw-like ovipositor and inserts an egg down into the plant tissue. After four days in the egg, the very delicate young thrips breaks its covering, forces itself out through the incision and at once begins to move actively about and to feed. Young thrips injure foliage and fruit rather than blossoms, and are usually to be found in terminal buds or on fruit under protection of the old blossom.

They remain in this stage about four weeks and on reaching maturity, with much stored up fatty tissue, leave the tree and seek a secluded place in the ground. They hold over as quiescent larvae for several months before changing to pupae. At present, July 21st, three months after leaving the trees, they are still in the larval stage and show no signs of developing wings. This thrips spends one or two months above ground, when it feeds ravenously, doing all its damage, then goes into the ground, where it holds over until the following year.

* * *

Cannot be Reached by Sprays.—Spraying for thrips, as many of us have learned from experience, is a very unsatisfactory means of control and for several reasons. All spraying must be done either while the tree is in bloom or while the tender foliage is just pushing out, hence the insect cannot but be a hard one to kill without doing injury to the tree. Secondly, their feeding habits are such that it is almost impossible to reach them. Thrips force themselves down into the bud or blossom and are thus protected. The injury is extremely rapid, three or four days being sufficient to entirely clean an orchard of its blossoms. It is necessary therefore to cover an orchard almost at one time and over a large area this would be impossible. The insects do not all leave the ground at once but keep coming up for several weeks and from this and from their habits of migration one may spray his trees, kill most of the insects and within a few days his trees will be as thickly infested as before. Sprays will doubtless be tried again, but they will be only partly effective; they can only lessen the numbers of the insect with little or no appreciable results and there is almost certain to follow injury to the tree. It is useless at this time to give the results of the spraying which has come under our notice this year; no one spray has proven satisfactory and under the conditions none can. The whole theory for controlling this insect by spraying is a wrong one.

* * *

Natural Enemies.—The subject of natural enemies for our insect pests is of consideration second to none and yet, for this particular thrips I fear we have a hard problem. Several common predaceous insects feed on thrips, but from the very nature of the life of the pest they cannot prove a successful check. A single thrips spends about a month on the tree and eleven in the ground, though as a species it lives some two and a half months on the tree and the rest of the year underground. A beneficial insect to be ef-

(Continued on Page 78)

News Notes from Florida

By Rev. C. J. K. Jones, Stetson, Florida

Another letter, full of newsy notes, is received from Rev. C. J. K. Jones, formerly of Los Angeles, but not at Stetson, Florida. Rev. Mr. Jones has become an agriculturist in fact, as he was in theory and knowledge when in California. We note in a recent issue of the Volusia County Record the following:

"One of the prettiest farming scenes in the county is out on the fine farm of Dr. C. J. K. Jones at Stetson. He has 20 acres of cow peas waist high, and just beginning to fruit. The Doctor will convert the greater part of it into hay, and the pea vine makes a most excellent hay. Dr. Jones proposes to have one of the model farms of the State. He has everything growing in the highest state of cultivation. He also has a crop of the Conch pea, which is the finest pea grown for table use." The notes which Mr. Jones sends to Cultivator readers are as follows:

The orange trees in Florida, where well fertilized and cultivated, are doing very well, in making new growth. The long drouth has been broken and the fruit is increasing in size rapidly. I note a good deal of rust on both oranges and grapefruit. I see no reason for changing my former estimate of the coming crop. As recently expressed in figures by one who has been over the ground pretty thoroughly, the crop will approximate 800,000 boxes of oranges and 175,000 boxes of grapefruit.

Speaking of grapefruit, there are extensive groves of this variety of citrus in Southern Florida. I recently saw notice of the sale of a 110 acre grove for $100,000, near Arcadia, in De Soto county. The purchaser is the owner of an 80-acre grapefruit grove in addition to his late purchase.

* * *

A friend in Southern California wrote to me a short time since that he had just applied muriate of potash with blood and bone to his orange trees. I immediately wrote to him that muriate of potash should never be applied to orange trees, or to any tree of the citrus family. It is a safe rule, also, to apply blood and bone only in very small quantity and at infrequent intervals. Of choice, I would never apply it to any citrus trees. Organic nitrogen should be used very sparingly. When used to excess it is the fruitful source of many diseases to our trees. Fruit from trees that have received it in liberal quantity neither ships well, nor does it stand up when once on the market. Such fruit also lacks character in its flavor. Moreover, trees fertilized with organic nitrogen feel low temperatures to a marked degree. I would prefer nitrogen derived from nitrate of soda and sulphate of ammonia. Stable manure, for the humus it provides, together with certain bacteria, may be applied once in three years, but not oftener.

The source of nitrogen has a radical effect in determining the health and character of the growth and quality of the fruit of citrus trees, as before stated. Some varieties can stand more organic nitrogen than others—for example, the Valencias are gross feeders and will resist ill effects of organic nitrogen better than the navel—but sooner or later all varieties are injuriously affected by the constant applications of organic nitrogen. I knew of a handsome grove in San Bernardino county that was nearly ruined by successive applications of blood and bone. The element of diseases, melanosis, and other troubles, would seem to be in the blood source of the nitrogen, as nitrogen, derived from bone in the mixture of a balanced fertilizer is not only harmless, but beneficial, and this notwithstanding the truthfulness of the general principle that the main source of nitrogen for the citrus family should be inorganic.

* * *

The question of humus in the orange groves of California is one of growing importance. Probably there is no method so cheaply available as planting Canada field peas, not later than October 15th. I would prefer them in the ground by October 1st. With a favorable season they should be ready—when in full bloom—to plow under by February 1st to 15th. These peas supply both nitrogen and humus. They may be fertilized with a mixture of six to seven per cent phosphoric acid (derived from acid phosphate) and seven to eight per cent potash (sulphate). In Florida beggar-weed (Desmodium tortuosuni) and crab grass (Panicum sanguinale) are the main dependence for ground cover and humus. These are either plowed in, or better, well chopped in with a cutaway harrow in October. They resolve in the soil quite slowly during the late fall and winter, but are ready for the use of the tree by early spring.

In Florida beggar weed is by the majority of grove men considered the only leguminous crop that is safe to put in an orange, or indeed, any citrus grove.

* * *

In Florida we are having unfortunate experiences with our seeds of various kinds. It seems impossible in the State, or out of it, to get pure seed of any sort. Here are some instances that have come to my notice. Oats bought of a reputable firm for Texas Red Rust Proof turned out anything but rust proof—although some of them were red, and they or their ancestors may have come from Texas—they were a failure. Beggar-weed seed was ordered in another case. Kaffir corn was sent instead. Again egg plant seed was ordered from another house; it turned out to be a purple weed! "Florida Favorite" watermelon seed was bought. There were four different kinds of melons and but few "Florida Favorites." From an old New York seed house, Mammoth Russian sunflower seeds were bought. Not ten per cent proved to be the Mammoth Russian. I have seen clover seed so foul with a mixture of grass and weed seeds that they made up the large majority—eighty per cent of the so-called clover seed. Our legislatures should pass stringent laws making seedsmen liable in pecuniary damages to the farmer and gardener whom they thus rob of his money, time, labor and crop. Of late many of these men have sought to escape responsibility by saying "We do not guarantee our seeds. You buy them at your own risk." This is not fair, for the planter of seeds assumes all the risk. The boycott is not American and yet it seems to be necessary for mutual self-protection, that the names of these unreliable seed dealers shall be passed from mouth to mouth until they show works meet for repentance.—C. J. K. Jones, Stetson, Florida, July 15, 1905.

PEACH PLANTING IN GEORGIA.

The prediction is made that Georgia will see its greatest planting of peach trees the coming season. The State claims to have within its boundaries some of the greatest peach producing belts in the world. One section, that of Perry, the shipping town of which has a population of only about one thousand people, claims to have a greater number of peach trees and ships more peaches and receives more more money for them, than any other section of the globe. There are in the one county of Houston over 4,000,000 of peach trees with an annual yield of about 900 cars. In that one section of Perry, it is estimated there will be 100,000 trees planted this coming season. One firm alone will plant over 3500 trees. The section mentioned has not been as yet infested with the San Jose scale and the growers are maintaining a rigid quarantine and are taking every precaution to keep it out.

According to the twelfth United States census, the value of the fruit of the United States was $131,423,517, divided as follows: Orchard fruits, $88,751,840; grapes, $14,090,937; small fruits, $25,030,711, and subtropical fruits, $8,549,863.

Of the $131,423,517 worth of fruit reported, California contributed $28,280,104, or 21.5 per cent; New York, $15,844,346, or 12.1 per cent, and Pennsylvania, $9,884,809, or 7.5 per cent. The five States of California, New York, Pennsylvania, Ohio and Michigan reported fruits of an aggregate value of $68,769,841, or 52.3 per cent of the total value of the whole country's crop. Measured by its relation to all the States in the production of fruits of all kinds, Georgia ranked in 1900 only twenty-ninth in importance; but in the production of peaches, the State ranked among the first, if not the first. Delaware and New Jersey, once peach centers, show a most remarkable decrease in the last decade, while the largest areas in the history of peach planting are reported in Georgia, Alabama, North Carolina and eastern Texas.

NOT ONE.

"Just one," said the lover as he stood upon the stoop with his girl; "just one."

"Just 1," said the mother, putting her head out of the bedroom window above. "Well I guess it ain't so late as that, but it's pretty near 12, and you'd better be going or her father will be down."

And the lover took his leave with a sad pain at his heart.

BEE NOTES BY THE WAY.

In my last article I referred to the fact that in the Lisbon district along the Sacramento river I saw no bees, and yet, from the great fields of alfalfa, the dry atmosphere, and the successful experience of Mr. Stevenson, not many miles up the river, I was convinced that that would be an admirable location for an apiary. As the cars sped us on over the wonderful Shasta route, alnog the upper Sacramento and the Klamath, in fact away up into Oregon and Washington, I was reminded many times of the opportunity, as it seemed to me, for the beekeeper to increase his belongings. Indeed, this was more or less true all through on the Northern Pacific railroad, and I am fully persuaded that our agricultural resources are as yet hardly touched. It seems to me that here is a splendid field for research by our Department of Agriculture to give us much valuable information. I have before referred in these columns to the fact that because a plant secretes nectar in one section of the country, it is no certain evidence that it will do so in another. We have noted that while alfalfa is a noted honey plant in the San Joaquin and Sacramento valleys, it is almost a failure as a honey plant in the alfalfa regions of Los Angeles county.

Thus we may never know whether any locality is good for bees until we have actually tried it. This prospecting, if we may use the term, is valuable for our whole people, and ought not to be the work of the individual. These fertile valleys of California, our sister States north and along the Columbia, Yellowstone and Missouri rivers, certainly give great promise for practical bee-keeping. How could our Apicultural Division of our Bureau of Entomology of the Department of Agriculture do a better service for apiculture than to demonstrate to the beekeepers of the country the exact apicultural promise of each section?

* * *

BEEKEEPING FOR BEGINNERS.

Fuel for the Bee Smoker.—We have all read of how we may save time by a stitch in time. Plan for saving time might often be employed with great advantage in many lines of our agricultural work. At this season of the year the bee smoker is constantly in use. Often much valuable time is lost in starting the smoker. Who has not been vexed, more than once, by reaching for his smoker, when the need was great, to find the fire out, the smoke wanting, and the angry bees most irritating. If at such a time the smoker could be lighted in a second, it would not only save time, but often serious vexation. For this purpose it is well to provide rolls of cloth—burlap is good—which may be ready at any time. These rolls are prepared as follows: Roll the cloth until the roll will just go nicely into the fire tube of the smoker. Secure the roll by tying with strings every three or four inches. By use of a sharp hatchet we now cut this roll into lengths just right for our smoker. We next dip one end of each roll into a strong solution of salt petre, when our smoker is ready for use. The salt petre makes it easy to light the smoker and so we save much valuable time. Such a roll will last for a long time.

* * *

When to Extract Honey.—I have often referred in these columns to the importance of delay in extracting our honey until it is fully ripe. In a recent number of the American Bee Journal, many of the leading beekeepers of the country give their opinion as to the amount of honey that should be capped over before extracting should be done. Some say when it is two-thirds capped, and thus on even to one hundred per cent. Mr. Dadant, who, perhaps, is as good authority as we have, states that he would not fix the time upon the amount capped over, but rather, upon the body of the honey. The extracting should always be delayed until the honey is thick and so thoroughly ripe that no one could object to its quality. It only remains to be said that nothing is so good a guide to complete ripening as that the honey should be fully capped over.

I am free to say that probably nothing has so damaged the reputation of extracted honey as premature extracting. The temptation to extract before the honey is fully ripened is by no means light. We save time in the uncapping, if the work is done just as the bees begin the capping, and the thinner honey is much more easily extracted. Yet, he who is the victim of this temptation, saves labor at a serious cost, not only to himself, but to the fraternity as a whole. It should be the aim of every beekeeper to make his product so admirable and perfect that its sale and use would always popularize this food.

* * *

THE OCTAGONAL SILO.

Of late there has been considerable said in the agricultural press favoring the construction of polygonal silos. So far as I know, I was one of the first in the country to construct such a silo. This silo is now standing within a few rods of where I am now sitting. The first silo I built was a square one which, though it has been used for years, is as good as ever. This was a plastered silo and by simply washing it each year with a cement wash, is ever ready for the silage. Yet we found from the first that there was too great a loss in the corners, no matter how much pains we took in filling. This was what led me to make my octagonal silo. While this was an improvement on the older silo, there was still loss, which led to nailing a beveled board vertically in the corners. This improved matters, but still it is far from perfect. I am sure no one can afford to build such a silo. Indeed, it is cheaper to build a round silo and then we have no corners at all. As I have already stated in the Cultivator, there are two styles of round silo—the stave silo and the one made of boards nailed on horizontally. In the next article I will give my reasons for preferring the latter, as I am requested to give our readers the best style of silo to build. I am free to say that where the dairyman can secure a crop of corn, he can never afford to dispense with this valuable adjunct of the dairy farm. Some of our best authorities, like Mr. Sessions and Mrs. Sherman, believe thoroughly in the silo, even the corn crop may now be utilized for this purpose. Some of our best feeders for the markets or shambles, are equally pronounced in favor of the silo. The importance of succulent, appetizing food cannot be over estimated. It is this fact that will always keep the silo to the front on the farm.

* * *

KIND OF PEAS TO PLANT.

Subscriber from Redlands states that he is unable to buy the small Canadian field peas, but that his dealer recommends the large Marrow fat, saying that the growth equals that of any variety. He asks my opinion. The great point is to get good growth. The advantage of the Canadian field pea is the luxuriant growth of the vines. The Marrowfats would be still better in the fact that the peas would be so large and valuable. I am sure no one makes a mistake in planting either of these varieties and in case we wish to sell the peas I should prefer the Marrowfats. I wish I could say something to induce all our orchardists to plant their orchards to peas the coming September.

* * *

THE SAGES FOR HONEY.

Mr. Milo Smith, La Crescenta, who keeps bees, writes that in his opinion, the black, or bald sage, is much superior to the white sage for honey. I have no doubt that the quality is as good, and, taking all the years together, from all reports, I presume the black sage is superior.

A PAPER-MAKING SPIDER.

In the heart of the African continent where no other paper is manufactured, the spider paper-maker does her quiet work. Back and forth, over a flat surface about an inch and a half square, on the inside wall of a hut, the spider slowly moves in many lines until the square is covered with a pure white paper. Under this she places from forty to fifty eggs; and then, to fasten the square of paper more securely to the wall, she makes a strip of paper about a quarter of an inch broad, and with this glues the square carefully around the edges.

When all is done, the spider, which is quite a large one—places herself on the center of the outside of the little flat bag so carefully made, and begins a watch which is to last for three weeks without intermission. Apparently the young spiders would have many dangers to fear, did not their anxious mamma wage a fierce war upon the cockroaches and other insects that come near. After three weeks of unremitting watchfulness, the mother-spider leaves her nest in the daytime to hunt food, but she always returns at night, until her young are strong enough to take care of themselves.

NUTRITIVE VALUE OF BREAKFAST FOODS.

In a bulletin issued by the Connecticutt Experiment Station regarding values of breakfast foods we note:

"In general the prepared cereal products are all wholesome and nutritious and when reasonable in price are economical sources of nutrients and energy, especially when compared with meats or green vegetables. The different preparations from the same grain resemble each other quite closely in actual nutritive value. A curious name or appearance or process of preparation does not indicate any extraordinary food value, and the intelligent buyer may make his choice largely in accordance with taste, distrusting the extravagant claims made for any particular brand. If he considers economy, however, he is hardly justified in paying for some brands prices which are equivalent to 15 to 20 cents a pound when other preparations of equal value may be had for 6 or 8 cents a pound. . . . The nutritive value of the 'malted' or so-called 'predigested' preparations is no greater than that of other preparations from the same grains. In most of the malted preparations the quantity of starch actually converted into soluble material is very small, and in some cases none has been changed.

"The thoroughness of cooking has quite as much influence upon the actual food value of the preparations as the small differences in composition. If the cereals are not thoroughly cooked some of the nutritive material will escape the action of the digestive juices. The partially cooked cereals should always be further cooked for at least as long a time as directed, and even longer cooking will be advantageous in many cases."

RANCH FOR SALE

13 acres 12 miles from Los Angeles, near Pacific Electric. Cement ditch and paid for, water 15 cents per hour. For particulars address owner. D. F. CONANT, R. D. 1 RIVERA, CAL.

CONTROLLING THRIPS.

(Continued from First Page.)

fective must in a way parallel the life-history of its host, which in the case of this thrips would be a difficult matter. Predacious or parasitic insects are able to attack thrips above ground, but, from the very nature of their hiding can hardly reach them at other times. So far as we know no insect can effectively control another if it must be a general feeder or if it must live for a time on other insects, while its real host insect is in an unaccessible form, as is true with this thrips, since for a time they are completely hidden away from the external attacks of their enemies. Thrips come to our trees in such numbers, so suddenly, and feed so rapidly that none of the present beneficial forms can prove an effective check.

* * *

Attack Them in the Ground.—From the foregoing it might seem an almost hopeless task to check the ravages of thrips either by natural or artificial means. From the life habits it is seen that the insect spends the larger part of its life underneath the soil, and it seems to me that this is the time to attack it. After the larvae has reached full growth, as stated, it leaves the food plant and seeks a secluded place in the ground. The insect to get below cultivated soil follows natural openings, such as cracks or holes made by other insects or worms and reaching a secure depth, from three to twelve inches, usually from four to six, it hollows out a small cell on the side of the larger opening and securing itself it awaits further developments. It naturally expects to come out the same way by which it has entered. The insect has mouthparts such that it cannot eat its way out and having no claws cannot dig effectively. We think if the ground is so disturbed that these natural outlets are broken up or closed the insect must remain within and die. 'Tis true that many thrips get below the ordinary plowing and cultivating line, below four or five inches, but we think if the ground above is thoroughly worked, later rains will so run the soil together that an effective covering will be established. The manner of cultivation which most of us have fallen into fits in remarkably well to give our thrips a long undisturbed period or rest. During and after May, when thrips are in the ground we give the soil nothing but light cultivation and besides at this time they are still in the larval stage and if disturbed seek another place of hiding. After this no cultivation is done until the last of February or March and this is after the insects have left the ground.

* * *

Early and Deep Plowing.—From all of our observations and experience fall or winter plowing and working the soil seems to be the most rational way by which this insect can be controlled, at any rate other than this we have no effective remedy.

SELLING OF DRIED 'COTS.

The pressure brought on the fruit grower to sell his cured fruit before its best price can be secured is a factor which affects the market for the fruit for those who can and do hold. The poorer man in need of immediate funds often accepts a low price, which in turn depresses all prices. This is proving an embarrassing factor this year with apricot growers. With a light hold-over, it is reasonable to expect a fair price, but the buyer wants anything but a fair price and in some cases is offering 5 cents or less. Such price will not leave the grower living profit, but the buyers are better combiners and better stayers than are producers.

To overcome the greatest objection to growers waiting for better prices, the banks of San Jose are proposing to advance to holders of dried fruit, funds on fruits placed in warehouse. The Nurseryman says: "Where the same are in good condition and housed in a good warehouse, under insurance policy, they will advance up to say 4c per pound. This will make it possible for the grower who must have cash immediately to go to his bank and borrow the amount required, using his fruit as a basis for the credit.

Under this proposition of the banks, if the orchardists are not satisfied with the opening price offered for dried apricots, there is still a possibility of their getting the funds necessary for immediate needs, and retaining title to their fruit.

It would seem probable that this willingness on the part of the banks to make advances on the dried apricots will have the tendency to raise the opening price."

Regarding the crop in the Santa Clara valley:

The crop is probably the largest ever gathered in the valley. It is estimated at from 350 to 400 carloads of 40,000 pounds each. That stands for 16,000,000 pounds of fruit.

"This is an exceptional crop; but ordinarily we have a bumper crop about twice in five years. There is never an absolute failure, but other years the yield will be diminished. The total crop for the State this year is about 90 carloads. The output is larger than the original estimate, and it also runs to large sizes. The quality is fine and the dried product is more satisfactory than the average. The foreign demand is very healthy. Under such conditions the growers should make some money on their 'cots, and they will in my opinion, if they take a judicious course of action."

The fruit is yet largely in producers' hands.

CALLIEPHIALTES MESSER GRAVENHORST.

A beneficial insect which will accomplish as much as we hope of the codling moth parasite, is worthy a good big name, but it certainly looks as if scientists have gone a little too far with "Calliephialtes Messer Gravenhorst." We were just getting used to Ephialtes carbonarius, but now the other and larger and unpronouncable name is given and said to be the correct name of the parasite.

May the little black beauty live long and prosper and continue to make holes in the codling moth and if necessary to encourage its existence we may cut off some of that name.

MORE INSTRUCTORS AT CALIFORNIA POLYTECHNIC.

At a recent meeting of the Board of Trustees three new instructors were appointed for the next school year, beginning September 13. They are such good people and so strong in their separate lines that they will greatly strengthen the school.

Miss May Secrest is to be instructor in domestic science and matron of the dormitory. She is a graduate of the Kansas State College with the degree of B. S. She afterward pursued graduate work in the same college and also taught domestic art two years as an assistant to Miss Howell. In 1902 Miss Secrest was graduated from the course in domestic science at Teachers' College, New York. The following year she organized the department of domestic science and taught the course at Stephen's Point Normal School, Wisconsin. Since 1903 she has been associate professor of domestic art in the Ohio State University.

Leroy Burns Smith is to be instructor in English, history and economics He was graduated from Cornell University in 1901 with the degree of A. B. In August, 1903, Mr. Smith entered the University of California as a graduate student in the department of education. He was immediately made a reader in education by Dr. Brown, head of the department. In January, 1904, Mr. Smith left the University to accept the directorship of the educational work of the Young Men's Christian Association of San Francisco, from which position he resigned on July 1, 1905, to come to the Polytechnic.

Mr. Herman B. Waters is to be instructor in electricity and physics. He completed the electrical course, with the exception of a thesis, at the Montana State College of Agriculture and Mechanic Arts. The year of 1902-3 he spent at Cornell University taking the regular electrical work and was graduated with the degree of M. E. Since leaving Cornell he has been continuously in the employ of the Missouri River Power Co., at their Canyon Ferry station—a 10,000 H. P. hydraulic plant supplying the city of Helena with light and power.

The Dinuba Advocate is rejoicing over the prospect for abundant crops and fruits in California this year, and with lark-like cheerfulness sings the following merry song:

"Fifty-four cars of watermelons have been shipped from this station in the last sixteen days. Express shipments of green fruit and table grapes go out on every train. Dried fruit is coming in to the packing house. Dairymen have plenty of alfalfa, a good output of butter-fat and good prices. The wheat delivered here is equal to last year. These together with a successful handling of raisins and a market for wine grapes should put our farmers on easy street for the next twelve months."

The weather and crop conditions for the week ending July 24 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—The weather during the week was warm and clear in the interior and cool, cloudy and foggy in the coast districts. Field fires destroyed several hundred acres of grain and feed in Calaveras and Glenn counties, and forest fires caused great damage in Mendocino county.

Grain harvest is completed in some sections and progressing in others. The yield and quality of wheat, barley and oats are much below early estimates and in some places the grain is said to be not worth harvesting. The hay crop is very large in nearly all sections and the quality excellent. Hops are making fair progress, but the present outlook is not satisfactory. Beans are in bloom and give promise of a heavy crop. Sugar beet harvest continues. Corn is in good condition and there will be an average crop.

The midsummer varieties of deciduous fruits are ripening rapidly and fair crops are being gathered. Pears are yielding better than expected and plums are fully up to average. Peaches and prunes are light in some sections and fair in others. Grapes were somewhat injured by the recent hot weather, but still give indications of a large crop. Citrus fruits are in good condition.

Eureka Summary.—Farmers are in the midst of haying; crop never better. Oats are ripening and some fields are almost ready for harvest. Potatoes are poor; other vegetables are doing well. Apples will be about an average crop. Grass in the interior is drying rapidly.

Los Angeles Summary.—Corn and beans are looking better than last year, but the weather is unfavorable for drying fruit. Oranges are dropping some. Beemen are busy slinging the second honey crop; the yield is heavy and quality fine.

CITRUS FRUITS

By C. A. Day. Pasadena

WHY SOME ORANGE GROWERS RECEIVE POOR PRICES.

I am very sure that every navel orange grower who is a reader of the Cultivator will read an article under the above heading.

Very frequently the grower lays the blame to over production, excessive freight rates, and icing charges, and bad management of those in charge of the packing houses. In very many cases the grower is confident that it is due to the methods of marketing and argues that a system of universal f. o. b. sales would be the panacea for all the ills of the orange industry of our State. Some things affecting returns are:

1. Off sizes, due to a poor setting of oranges, resulting in large sizes, discounted by the eastern trade.
2. Puffing of oranges; resulting in lowering the grade and carrying qualities.
3. Early dropping of oranges, due to climatic conditions and improper culture.
4. Careless picking, giving long stems and clipper cuts, causing decay.
5. Excessive freight rates and icing charges.
6. Careless, rough handling of the fruit.
7. Poor carrying qualities, due to improper culture and fertilization.
8. Black scale with undue draft on the vitality of the tree and decay from washing and extra handling.
9. Poor packing and grading.
10. Coarse, inferior fruit, due to improper culture and fertilization or soil conditions.

* * *

There may be other reasons, but these are enough for a starter, I will frankly admit that I was surprised at the long list of good reasons why navel oranges of the season just closed did not give better returns to the grower. In the matter of culture, handling and marketing of citrus fruits we have four striking object lessons in the case of Mr. Mills, of the Arlington Heights orchards of Riverside county, C. C. Chapman of Fullerton, Mr. Leffingwell of Whittier and Mr. Teague of Santa Paula. In these we have instances of correct culture and handling of the lemon and orange crop for market, due to intelligent management of large orchard holdings, which has resulted in good returns to the owners. On the other hand we have the great mass of small growers that market their crop through associations, of the exchanges and various other organizations. These small holdings make up a medley of ways and means in culture and handlings, with corresponding results. The membership of an association, dissatisfied with the returns for fruit, frequently lays the blame for this to overproduction, excessive freight rates and mismanagement of the packing house manager or foreman.

I would recommend every citrus fruit grower who reads this article to carefully scan the ten reasons given why the citrus fruit crop of California does not give better returns to the grower and see whether any of the fault lies in the individual. The question that naturally arises is, where does the principal fault lie, in the continued improper culture, mismanagement and improper handling at the packing house, or the excessive rates for freight and icing. My answer to this very important question is in three words. "With the grower." From what I personally know of the average citrus fruit grower I can easily imagine that there will be a strong protest against accepting this answer to the question.

Now let us divide the question into three sections: Excessive freight rates, mismanagement of packing house, and improper culture. Now as to item No. 1: The President of the United States has declared in favor of granting to the Inter-State Commerce Commission the power to fix and establish freight rates.

Have the citrus fruit growers backed up and supported the President's policy with energetic and well organized effort? No. Has there been an effort made to organize the various branches of fruit growing and agricultural interests of the State and country at large? No. Has there been any decided effort to unite the citrus, raisin, prune, fresh fruits and vegetable interests of the State to secure the much desired amendment to the Inter-State Commerce act? No. Has there been an organized effort to unite the grain, stock, dairy and fruit interests of the country in concentrated movement to influence legislators to support the policy of the President? No.

The Inter-State Commerce Commission has declared in favor of reduced freight rates on citrus fruits, but it has no power to enforce the decision. It is true the California Fruit Exchange has passed resolutions in support of the President's policy of giving to the Inter-State Commerce Commission the power to fix and establish freight rates, and has sent these resolutions to the various associations of the exchange with request that they pass similar resolutions. The exchange, however, represents only one half of the output of the citrus orchards of California. Already the agents of the railway corporations are approaching business men and the officials of various organizations to secure support in opposition to the proposed amendment.

The present conditions are favorable for us to secure the desired legislation. President Roosevelt, with his fearless independence of character, brings to bear the whole power of the present administration and we, failing to actively co-operate, will let an opportunity pass that may never come again. The agricultural press of the whole country should strive to arouse public sentiment in behalf of the proposed measure for relief. Failing to act, the citrus fruit grower can blame no one but himself for a probable continuation of the present rates for freight to eastern markets.

Now as to possible mismanagement at the packing house: In the exchange association the membership annually elect the board of directors which elects the president and secretary and appoints a manager. The duty of the board is to see that the affairs of the association are properly managed and the membership of the association should hold the members of the board responsible for the proper conduct of the affairs of the organization. Failing to do this the individual grower is responsible for the continued mismanagement of the affairs of the association. From personal interviews with the managers of different associations under the exchange, I learn that the managers' greatest trial is the quality and condition of the fruit as it is delivered at the packing house. The individual grower will deliver fruit at the packing house with long stems or clipper cuts, in some instances puffed, of inferior carrying qualities; rough, coarse fruit covered with smut from the black scale or off sizes, and then complain because he, the grower, did not get better returns for his fruit.

In many associations an effort is made by grading extra choice and extra fancy to give the grower of the better quality of fruit returns in proportion to quality. But long stems, clipper cuts, and fruit with poor carrying qualities or fruit roughly handled, or smutty fruit that will require the extra handling of washing, will largely augment the sum total of decay of the fruit of the association and this loss must be proportionately borne by all.

The remedy for this state of affairs is for the growers of sound fruit, properly picked and handled, to demand better culture and careful handling on the part of all whose fruit is pooled with theirs. The time is coming when associations of growers will have to enforce proper culture, clean fruit and careful picking and handling of all fruit. In some cases this plan is now being carried out, that is, that only fruit from well cared for orchards are admitted to the association pool. The advantage of the large grower who packs his own fruit is, that he has full control of the orchard culture, picking, handling and packing of the fruit.

The reports of the condition of oranges on arrival in eastern markets during the season past show a percentage of decay that has materially lowered the average returns for the whole crop. It is my belief that a large percentage of this loss by decay can be prevented.

DO ORANGES PAY?

Editor Cultivator: Some orchardists say yes, some say no. The farmer who got his returns for oranges in red ink, sadly answers in the negative. There are several elements that determine results. The farmer, the soil, the season, the market, the commission merchant, the business capacity of the grower and, last, but not least, the railroad.

The Valencia is rapidly coming into favor. Many orchards are being budded over. This tree is generally considered a "shy" bearer, but farmers are coming to see that if they can realize $2.00 net one in two years, it is better than 50 cents every year. So hundreds of acres are being budded to Valencias. Mr. Isaac Overholtzer, of Covina, received last year $5000 from about five acres of Valencias. It is said that $1500 an acre has been realized from this orange. Some of the land in this thriving section is peculiarly adapted to this fruit.—O., Covina.

Expert Budding

I am prepared to bud small or large citrus trees.

FLORICULTURE AND GARDENING

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

CHRYSANTHEMUMS.

During July all chrysanthemums should be cut back; even now it is not too late. If your plants have not been so treated, you will probably get flowers before the hot weather is over and they will be small. If cut back now and given plenty of food and drink there is time enough to produce flowers of the first water for October.

As the plants grow up they should be staked and tied, one stalk or stem to a stake. The 'mums on the farm usually do not grow so tall but stakes from split shakes will be high enough

Autumn's Floral Queen.

With the grower some sorts often run up to eight feet, but this is not general and is almost inexcusable. Plants should be tied with raffia, procurable at any seed store, or with strips of cloth torn into quarter inch widths.

No good results can be obtained without disbudding. All the buds except the few on top which you wish to flower should be removed. This is easily accomplished as soon as the lower buds show by "rubbing" them out with the finger tips, as they are very brittle. Growers recognize two kinds of buds: Terminal, and crown. These terms are easily understood, the one large bud which first comes, at the end of each shoot is the crown bud; the secondary ones are the terminal buds, of which several surround the crown. In the early sorts it is best to use the crown buds.

The crown buds will begin to show in August, though in fact on some varieties they are formed at any time during the summer, but the crown buds, if taken before August 25, are liable to produce imperfect flowers. A crown bud may be distinguished when young by the buds directly below or surrounding it being growth buds. If these growth buds are not taken off they will produce new shoots, and the crown bud will dry up, it being really an abortive flower bud, and would never produce a flower without the kindly aid of the grower. These crown buds, being produced fully two weeks before the terminal buds begin to appear, if taken, they will produce flowers two weeks earlier than if terminals had been taken.

For midseason and late varieties, it is just as well to take the terminal buds. They appear in a cluster, and are all flower buds. These are the buds that are usually taken. It is more work to disbud these, as new buds are continually forming, and the plants have to be gone over several times. When the crown bud is taken, no buds are formed under it, and if all side shoots are brushed off they will require but one disbudding. Then the leaves begin to assume a dark, leathery appearance, and you may know all the strength of the plant is being concentrated in the flower, and it is likely to be a good one.

Keep the plants fairly well watered at present and feed lightly, but so soon as the first buds appear, feed heavily. Usually you may get plenty of good stable manure on the farm, and nothing is better for general feeding. As growth continues, feed more and more. If you wish to get unusual results, feed a small quantity of bone meal twice a week, worked into the soil around base of plant. This feeding must stop when the buds show color or you will "burn" the buds. Heavy watering must continue until the flowering season is over.

The best philosophy—a contented mind.

FLOWERS ON THE FARM.

There are few things that mark the progress of civilization more than a correct taste in architecture and gardening. So long as men are indifferent to the appearance of the house they live in, and the grounds that surround it, they will rarely exhibit a true taste for anything else. We are happy in the belief that our farmers are gradually improving in this respect. As intelligence and wealth increase, so do refinement and good taste.

The love of flowers and the cultivation of them is an evidence that true and pure sentiments are in the heart; that a love for the beautiful has dawned there, and that the elements of progress are at work. The scenes and circumstances by which we are surrounded have much to do, not only with our character, but with our happiness. On this account we should do all in our power to make our homes attractive; to adorn them with those charms which good sense and refinement so easily impart to them. It costs little to surround our homes with these simple beauties that delight the eye far more than expensive objects. Nature delights in beauty; she loves to brighten the landscape and make it agreeable to the eye; she hangs the ivy around the ruin, and over the stump of the withered tree twines the graceful vine.

The care and culture of flowers elevate and purify the mind, and give the dusty walks of life many a charm that cannot be found where they are wanting. They have a refining influence on children, tending to soften and polish their manners, and to inspire them with cheerful views of life.

It is a law of our being that we become attached to those objects upon which we have bestowed labor, and on which we are expending care. We love the trees our own hands have planted, the vines we have cultivated and trained over our doorways, and over the trellis our own hands have constructed.

Cultivated flowers are evidences of high civilization; they are a sort of floral thermometer, indicating in some degree the intelligence and refinement of the people; and their indications are as significant as are the evidences afforded by architecture, painting, poetry, or any of the sciences. The lessons of these gentle teachers are having an influence on the habits and manners of our people.

There is scarcely a farm house now but has its flowers. They give a pleasant and cheerful aspect to the homestead, and attract the grateful admiration of the passing traveler. Their almost universal cultivation indicates a refined taste and higher intellectual attainments. Such evidences of improvement are full of promise for the future. The thriving occupants of residences in the vicinity of all our larger towns and cities are doing much by their example to stimulate the farmers in this direction. The creation of beauty which wealth and taste have produced, attract their attention, awaken in them the love of the beautiful, and lead them to attempt their reproduction on a cheaper and simpler scale.

Where there are flowers you will see more order about the buildings, an air of tidiness, thrift and comfort, and better farming generally; and in the dwellings the families are more intelligent, comparatively refined, and not unfrequently imaginative and poetical. Strange as the assertion may sound to some, it is nevertheless true, that if these last two qualities were more generally prevalent and cultivated on the farm they would tend to keep thousands of farmers' sons and daughters from deserting the old homesteads.

The cultivation of flowers and a better knowledge of them will not only have a happy, but an enduring influence. It will affect the character of farms and homes. Instead of unenclosed dooryards, where stray cattle and gabbling geese are at home, and old wheels and rambling woodpiles skirt the house in dire confusion, while huge dogs guard the doubtful way to the door, there will be a spot sacred to "fruits and blossoms that blush in social sweetness on the self-same bough." These will not only attract and please the traveler but will give the country house an advanced money value.

General Agricultural Notes

CONSTRUCTING CEMENT FLOORS.

The sub-grade of the floor, or the height of the earth below the floor, must be about one foot below the proposed level of the finished floor. When the ground has been excavated or graded to the desired height or depth a filling should be made of either cinders or sand (preferably the former because cheaper) thoroughly tamped or rammed to a uniform thickness of six inches. If necessary, water may be added to assist in compacting the underfilling of cinders. After this is done the concrete to a depth of five inches is put on, prepared as follows.

You may use any standard brand of Portland cement and to one part of cement add seven parts of gravel made up of good, coarse, sharp sand and pebbles up to two inches in diameter. Spread the gravel on a platform to an even depth of a few inches and upon this spread the cement evenly with shovels. Then work the cement thoroughly into the gravel by turning the two together several times until the whole is of a uniform color. To this mixture add enough water to make it easily handled and so it will quake under the tamper and the water flush to the surface, when tamping is complete. Do not wet the mixture until ready to use it and the suggestion is made to have it in place and tamped in one hour after wetting. The mixture must be turned several times after the water is added to make it evenly wet. The concrete is put in place in sections five inches deep and six feet wide crossways of the stable floor. Commencing at one end, place a board five inches high six feet from the end and fill the section to the full depth as you go along. When one section is filled and thoroughly tamped until it quakes move your board ahead six feet and fill in the fresh space. Sections may be less than six feet wide, but should not be more. When the concrete is in place and is still green, or has set for twenty-four hours, you are ready to put on the skim coat. This is made up of sand and cement in the proportion of two sand to one of cement, mixed to a good, even mortar, spread on with plasterer's trowel to the depth of one inch and finish smooth like a cement sidewalk. Make no effort to give the concrete a smooth finish, for the cement coat gets a much better bond on a rough surface. A good way to roughen the surface for the skim coat is to walk around on your heels while the concrete is being tamped into place, but on no account disturb it after setting has begun, or you will spoil it by preventing further setting. In putting on skim coat use a one-inch strip and apply mortar as thick as a strip.

After the skim coat is on and smoothed down it must be roughened to prevent stock from slipping. This is done as follows: To a piece of six-inch planed board, one foot long, fasten with small finishing nails triangular shaped strips as long as the width of the board, one-fourth of an inch deep and one-fourth of an inch wide at the base, spacing them about two inches apart. At one edge of the board the strips are beveled off at a good angle so that they will not catch the cement when the corrugations are made. When the "corrugator" is made draw across the freshly troweled surface coat and the strips will cut ditches one-fourth of an inch deep and one-fourth of an inch wide at the top, which will make a surface sufficiently rough to prevent the floor being at all slippery.

There are, perhaps, some general things that could be suggested and among them that the floor may be sloped a trifle so that no liquids will run under the feet of the stock. Just at the back edge of the stall you may put in a gutter that slopes each way from the middle to a drain previously put in under the floor foundation, or it may run the whole length from one end if the stable is short. It may be necessary to put in two or even three drain pipes if the stable is long and this would make the gutters short and shallow, which is more desirable. —Iowa Homestead.

RANGE OF WHEAT.

From the study of many facts connected with the growth of wheat in temperate and tropical climates, we are led to believe that in the United States the only positive limit to its cultivation on the south is the northern bounds of humid tropical heats, while on the north it may be grown to the utmost northern extremity of Maine, latitude 47 degrees, 30 minutes, where the mean temperature for May, June and July is but 56.11 degrees, and that for the warmest month, July, 62.30 degrees Fahrenheit. The northern boundaries of the United States are, however, by no means the northern limit of its culture. Wheat is grown on the Saskatchewan river, in the territories of the Hudson Bay Company, near Lake Winnipeg, in latitude 54 degrees north, where the months of May, June and July have a mean temperature of 57.11 degrees, and July enjoys a mean of 61.8 degrees.

On the plains of Bogota, where the temperature rarely exceeds 59 degrees, wheat is reaped in 147 days, having been sown in February and harvested the last week of July, the mean temperature for the entire period having been 58 degrees and 59 degrees. At Quinchuqui the vegetation of wheat begins in February and ends in July, at a mean temperature of between 57 and 58 degrees Fahrenheit. In England, the summer of 1853 was in many places at too low a temperature to ripen wheat, and the deficiency was general, and said to have been from one-third to one-half of the usual product. The mean for the months of July and August were 57 and 59 degrees, respectively, or two degrees below the usual average. From the above comparison of data it appears that wheat cannot be successfully grown where the warmest month of its growth, or that wherein the grain is maturing, falls below 60 degrees, or the mean of its period of growth below 56 degrees.

At Sitka, in Alaska, latitude 57 degrees, the mean of 39.7 degrees for the year has been observed, and a summer mean of 51.5 degrees, yet wheat will not ripen, because the warmest month reaches but to 59 degrees Fahrenheit, though two months were maintained at nearly this mean heat through ten years of observations.

CLIMATIC INFLUENCE.

While the most important climatic influence is temperature, the climate that would result from latitude alone is greatly modified by the presence or absence of extended sheets of water; and the distribution of heat through the year, from any place whatever, depends essentially on its proximity to, or distance from, the ocean or large lakes, and the relative frequency of the winds that blow over them. The equalizing influence of large bodies of water, the temperature of which is less liable to sudden changes than the atmospheric air, is quite apparent. While in Ireland and the southwestern part of England the myrtle grows in the open air, as in Portugal, fearless of the cold of winter, the summer sun of these so genial isles does not succeed in perfectly ripening the plums and pears which grow and ripen well in the same latitude on the continent. On the coast of Cornwall shrubs as delicate as the camellia and orange are green throughout the year in the gardens, though in a latitude at which, in the interior of the continent of Europe, trees the most hardy can alone brave the winter cold. The mild climate of England cannot ripen the grape almost under the same parallel where are grown the wines of the Rhine, nor will our Indian corn ever mature or attain there the size it will reach on our most northern border or in Canada.

TO PROTECT TREES.

The following protects trees from rabbits and mice. Take milk fresh from the cow and add dry yellow ochre until it makes a thick paint, apply to the trunks of trees and lower limbs on the low headed trees, with a paint brush, being careful to get it well down to the ground. It will stop rabbits if applied even after they have begun to destroy the trees. Do not add oil of any kind to the above as it would fill the pores of the bark and injure, if not kill the trees.

The world's production of meat, since 1840, has increased fifty-seven per cent, and the production of grain four hundred and twenty per cent.

Your life is what you make it.

Shams Going.—We don't know but our readers think the Cultivator pessimistic, because it treats of living issues in a somewhat ungloved manner, stating its opinion of things, as it would like to see them changed, where it believes they need changing.

But with all the upheavals in public mens' lives, and all the exposures in business affairs we are of the opinion that good will result. This old world is not going to the bowwows in one grand convulsion. It will right itself by and by, and come out all the cleaner and better by the shaking up it has received. The war between Russia and Japan, while terrible in its bloodshed and loss of treasure, will make of Russia a new nation, in which liberty will be granted the serfs and new impetus be given to every avenue of business and condition of life. The exposure and punishment of some of our well known men for dishonesty in public affairs will serve as a lasting warning to others to "get busy" along legitimate lines and cease their unholy attempts to get rich at the expense of their honor and the pockets of their constituents. The insurance world is just beginning to get its legitimate deserts for the evils which have grown up under its system. Before the public is through with it half the old managers of most of the companies will be retired from business, and the other half will be studying the language of some far away country, where no extradition treaty exists, or pacing the cells of some state penitentiary here in the United States. The beef trust will be bursted, and the combines will be seeking to get from under as fast as they can devise ways and means to do.

The plain truth is, the people have become aroused, and woe unto the evil doers because of the wrath of the injured. The great American public has been fooled a long time, but not all of it, and now that the whole country is afire, look well to the evil. The New York Sun, in an editorial on the shams of the day, says well and truly:

"The exposure of wrongdoing was never more persistent or relentless. Not the wrongdoing, but the exposure as a moral measure is the basis of moral hope.

"They have been turned on by the public demand. The demand has come from an honest public. It has been uttered through honest men and honest newspapers. The 'ado' is health. The fact that it prevails is a demonstration of honesty. The fact that it is bound to win involves the triumph of honesty. The fact that a few of the wicked and more of the weak are thrown down and run over is a tribute to inexorable integrity and to the vivid intelligence of the people at large and of journalism, and of reformers who are representing the people.

"Old-fashioned honesty is in the ascendant. Old-fashioned scorn of dishonesty and contempt for purchased power, purchased conspicuity, purchased praise, purchased immunity are abundantly attested. There should be contempt for the wicked, pity for the weak, charity for all, but justice also for all to the limit."

The Cultivator has faith in the judgment of the people, in the end. We shall have some trouble with dissatisfied labor agitators, we may see some blood shed in the great alien cities of the country, but finally these troubles will pass away, a better understanding obtain between employer and employee, honesty come back in business, and the world go forward to greater and grander things.

* * *

Antics of the Beef Trust—The Federal grand jury which found indictments against the leading packers of Chicago for alleged violation of the Sherman anti-trust law, is said to have spent more time on the examination of these cases than any other cases ever brought before a Federal jury.

They summoned leading agents of the big houses, from one end of the country to the other, took testimony in depositions and so framed the indictments as to cover all the points of the statutes violated. Notwithstanding the alertness of the government officers, however, there is danger that the indicted parties may escape their deserts, for they are prepariug to throw numerous legal obstacles in the way of the prosecution of the cases, one of which it is asserted wil be an application for an injunction to prevent the proof of any violation of law. The ground for this somewhat novel contention is that since the packing companies are acting under a permanent writ of injunction issued by Judge Grosscup that any further action should be confined to contempt proceedings an dthat criminal prosecutions are barred.

The result of the trials of the members of the beef trust will be watched with interest, for it is well understood that no obstacle will be left by the combine, whose future liberty from fine and imprisonment, or both, depends on their ability to escape the clutches of the law. The officers of the government must be exceedingly adorit or the indictments will be without avail.

* * *

Campaign for Pure Milk.—The efforts of the Board of Health of the city of Los Angeles to renovate the dairies, so that only pure milk shall be sold within the city is commendable. The only regret is that its power does not extend throughout the county, so that every dairyman, or every individual selling milk, cannot be held responsible to its rules.

It goes without saying that gross carelessness is frequently manifest in the smaller dairies of the county, as well as in the larger ones, which supply in quantity milk to the city trade. If the campaign which the city health department has inaugurated against infected milk will only extend to the country, it will not be long until Los Angeles county will gain the reputation of having the cleanest dairies and the purest milk supply of any county on the Pacific Coast. There is not the least doubt in the world that infected milk causes more deaths in children from intestinal troubles, like cholera infantum and dysentery, than any other single cause, and more deaths from typhoid fever in grown people than the public realize.

It is therefore of first importance to the health of the community that we have pure milk, and the efforts of the health board to secure it is deserving of commendation. Of course, there are many big supply houses where the greatest caution always exists; these are not affected by the crusade of the officers of the health department, but the careless dairyman who disregards the rules of health, and thereby spreads disease from his milk, should be made to comply with the rules governing the care of cows and milk, or he should not be permitted to dispose of his product.

There are a few simple rules which, if he would follow, would render him practically immune from the charge of unsanitary conditions and from the danger of selling infected milk. These rules may be summarized in brief:

Thoroughly clean the corrals, night and morning, cart off all manure, so that cows may not lie down in it. If the cows are stanchioned, the floor, which ought to be tight, or of cement, should be so made as to carry off the urine with the droppings. Urine will attract flies in greater numbers than manure and both will breed bacteria second only to warm milk when left exposed to the action of the sun and flies. Corrals, sheds and barns where cows are kept, should be treated to whitewash frequently. Slacked lime lightly sprinkled on clean sand ought often to be spread in inclosures where milk cows lie, in order to keep the ground in a healthy, absorbent condition. The dairyman may think these suggestions entail too much labor, but if he will try them carefully, he will note the healthy condition of his herd and the increase in its milk flow.

In this same connection, it is well to observe that the udder of the cow should never be washed just before milking. Always wash and wipe dry a half hour previous to milking, so that no dirt can attach to the bag to be pulled into the pail. Some dairymen prefer to brush the udder before beginning to milk, but as this sometimes induces nervousness in the cow, best authorities discourage the use of the brush.

There are also a few simple rules for the care of milk which should be imperatively followed if quick souring is to be avoided. Thoroughly cool the milk in the cans by setting in a trough of water from a half to three-quarters of an hour. If the cans have been well scalded in a solution of sal soda and thoroughly rinsed and kept tightly covered from the air and then cooled by placing them in a water trough, milk will keep sweet from 12 to 24 hours longer than it does where these suggestions do not obtain. The Los Angeles Board of Health recommends that every bucket of milk shall be strained into a container to avoid the danger of flies coming in contact with the milk. The recommendation is also made that straining shall be done in a room from which flies are excluded and that every utensil used about the milk shall be made absolutely clean. Cooling milk before delivery is of the greatest necessity, because it lessens the liability of gas forming and bacteria developing in the cans, which, of course, are shaken in the delivery wagons and the milk thereby disturbed. If milk sours over night the fault in in the use of dirty utensils and the customer should report the deliveryman to the health board in order that an inspector may be sent to that dairy to correct the neglect.

We cannot be too careful about our milk supply. Too often it is the food of children whose sensitive stomachs absorb the poison in the fluid and who die as the result of careless and unsanitary conditions of the dairy. We would not recommend widespread publication of those whom the Board of Health are compelled to punish, for the reason that a scare over milk supply will injure the dairy business in general, but we would suggest that the Board of Health insist, with rigid impartiality, on every dairy which supplies milk to the city, observing strictly the rules governing sanitary conditions about the place, in the buildings and in the care of the milk. Only by so doing will the public enjoy immunity from diseases which find their origin in the milk we drink.

* * *

Looking for Results.—The whole State is looking forward with interest to the National Irrigation Congress, which will be held in Portland, Oregon, from the 21st to the 24th of August.

It promises well. The circular sent out, detailing its work, forecasts a program of much merit. There will be five distinct sections, with a specialist in charge of each section, and each one will endeavor to bring out the best and most reliable information it can obtain on irrigation matters. Reinforcing its study with so much of practical irrigation display as may be afforded by the means at command. The government will have a display on the exposition grounds which will demonstrate the operation of reclamation work to date, and this alone will be of such general interest as to command wide spread attention from all interested in this branch of the general irrigation work. Taking the congress, as a whole, the public may expect beneficial results from its deliberations, and the irrigation movement receive a valuable impetus all along the line.

NEWS OF COUNTRY LIE IN THE GOLDEN WEST

HORTICULTURE.

Prune buyers are reported in the Pajaro valley, and the sale of the crop on the trees has begun.

The California fruit distributors started sixty-two carloads of fruit to the east last Thursday.

The apricot crop in the Pajaro valley, for this year, is estimated at 500 tons of green fruit, making about 100 tons of dried fruit.

The olive crop in Santa Barbara county promises to be one of the largest that has been gathered there for several years past.

Indications now point to the largest apple crop in the history of the Pajaro valley. Three thousand car loads is the estimate for this season.

The assessor's returns from Riverside county show that there are a total of 1,353,911 orange trees and over 125,000 lemon trees in that county.

The total number of carloads of fruit shipped at Vacaville so far in the season, ending July 20th, amounted to 493 cars, as against 269 at same date last year.

The warm weather is causing fruit to ripen vrey rapidly about Chico and the cannery there is running full-handed from dawn to dark to handle the crop.

The stockholders of the Highlands Orange Growers' Association, at a meeting last week, decided unanimously to rejoin the Southern California Fruit Exchange.

The walnut crop of Southern California is now estimated to be 25 per cent short. The shortage is caused by the backward spring. Very little injury is reported from blight.

San Bernardino county has authorized the horticultural commission to expend a sum, not to exceed $3000, for new tents for fumigating trees and new spraying machines.

Only about 12 tons of cherries were shipped out of the Yucaipe valley this season, which is but a small fraction of the usual crop, however, good prices were received, which will help out the growers.

Peaches are being shipped from the north to G. H. Waters, at the Pomona cannery. Mr. Waters will receive 400 tons during the season. That cannery employs about 500 hands during the busy season.

The Sonoma County Farmer reports that the prune crop of the Healdsburg section, which is estimated at three hundred tons, has been sold at $40 a ton, cured. The crop is small and runs to large sizes.

A fancy price was received for a car of lemons sold at Boston, Monday of last week, which is perhaps the highest price received so far this year. A car of 364 boxes from Highlands sold for $2017, gross.

It is announced that the Golden State Packing Co. will, during the coming year, erect one of the largest canning establishments at Yuba City of any in that part of the State. It is stated that $1,000,000 is back of the enterprise.

J. A. Cover, of Modesto, has placed an order for several thousand grafts of English walnuts with a Rincon grower. He will try the experiment of grafting the soft shell walnut into the wild stock and endeavor to raise the marketable variety.

M. B. Waite, government pathologist from Washington, is expected to visit California shortly to confer with Professor Smith of the University of California, and a campaign will be planned against the pear blight, to be put into effect next winter.

A new company has been formed at Riverside by Messrs. Frank Cuttle, W. W. Wilson, George Frost, Frank F. Chase and F. P. Chase, to be known as the California Orange Co. One hundred and sixty-three acres of first-class orange land south of Bloomington have been secured and will be planted to oranges. Irrigation wells and cement pipe are being put in to irrigate the tract.

AGRICULTURE.

It is stated that the farmers in the Imperial valley will ship 400,000 sacks of barley this season.

The recent hot spell in this State was a benefit to the sugar beet and bean crop on irrigated lands.

The potato crop around Watsonville, San Jose, Gilroy and Hollister is reported very abundant and of excellent quality.

Exceedingly hot weather prevailed at Yakima, Washington, last week, causing late sown grain to be badly damaged.

Twenty-five hundred sacks of wheat are being received daily at Guernsey, from the great wheat fields in the lake country, Tulare county.

Fresno growers are now harvesting the largest melon crop ever grown in that county. Prices are reported low, running from $10 to $14 per ton.

An experiment is being carried on at the Washington State Agricultural college to determine the possibilities of the potato starch industry in that State.

The ranchers living on the banks of the Santa Ana river, in Orange county, are having estimates for building levees to confine the river within its banks.

Eight threshing outfits are at work around Oxnard and so far the barley fields are turning out better than expected, some going as high as forty sacks per acre.

Last week the Exeter Sun issued its elegant midsummer number of twenty pages, descriptive of the fine agricultural and fruit section in the western part of Tulare county.

The barrier at Daguerre Point, in the Yuba river, has proved a success. A wide expanse of river bottom land will be reclaimed, which will support a large number of small farms, gardens and berry patches.

The canteloupe growers around Brawley met last week and organized an association. Peter P. Hovley was elected president. A. W. Applegate, vice-president, and F. H. Stanley, secretary and treasurer.

A San Francisco syndicate last week purchased five thousand acres of land on Sherman island in the Sacramento river, at a cost exceeding $80,000. The syndicate proposes going into the cultivation of asparagus on an extensive scale.

The hop yards in practically every district of Oregon show a worse condition than any were in during the mouldy year of 1897. Present conditions are very gloomy for the coming crop. One-half the crop may never be picked.

A new cannery, twice the size of the one recently destroyed, is to be built at Napa Junction and completed in time for next year's business. In addition to the cannery business the company will plant two hundred acres to asparagus.

The U. S. Department of Agriculture asks San Diego to furnish it with five acres of land with free water for fifteen years, on which to experiment with spineless cactus, to find what species is best adapted to the hills and valleys of Southern California as a stock food.

The hop growers of Oregon, who recently organized into an association and controlling the output of over two-thirds of the Oregon acreage, now ask the California growers to combine under the same conditions and become affiliated with a movement to handle the crop and control the prices of the entire output of the coast.

LIVE STOCK.

B. Schuler has recently commenced the erection of a new cheese factory near Galt.

A movement is on foot to start a co-operative creamery at Occidental, Sonoma county.

The Buena Park condensed milk factory shipped two cars of cream this week. The capacity of the factory is now eight hundred cases a day.

M. E. Nicholson, of Mendocino county, sheared 534 head of sheep and had 2702 pounds of wool, all first class. Over five pounds of wool per head is a good clip.

Sheep owners around Yuba City have commenced the fall shearing. Reports are that the clip is good and the present price from twenty to twenty-two and a half cents per pound.

Dr. H. S. Warren Johnson has established a goat farm near Los Gatos, California, and has now fifteen milkers. Among them are some fine imported stock, one from the island of Malta, which is valued at $150.

MISCELLANEOUS.

Ferndale fair, in Humboldt county, will open September 5th and close on the 9th.

The assessment of Orange county this year was $13,332,000, which shows a gain of $304,000 over last year.

Three new instructors have been appointed for the next year for the State Polytechnic school at San Luis Obispo.

This year's assessment of Alameda county shows a net gain in value of $9,202,000 against that of last year.

The assessment roll of Tehama county shows a total valuation of $10,908,000, which is a substantial gain over last year.

The streams around San Bernardino were stocked with 120,000 fish from the State fish hatcheries at Sisson, last week.

The Native Sons of Marysville will make the attempt to gather one of the best exhibits ever placed by Yuba county, at the coming State Fair.

The sockeye salmon are reported in great numbers in Washington streams this summer and all canneries have all the fish they can handle.

The American Pomological Society meeting has been postponed from August 8th-10th, to September 19th-21st, and will be held at Kansas City, Mo.

No district fair will be held at Fresno this fall, owing to the cutting off of the appropriation of $2000 from the State by the legislature last winter.

The State Grange of California will hold a three day's session, commencing Tuesday, October 3d, at Napa. There are now forty-eight granges in the State.

The local grange, the county board of supervisors and the board of trade at Hanford have all joined in asking the State to continue the Tulare experimental farm.

The Macdonald ranch of seven hundred acres near Buena Park, Orange county, was sold last week to H. B. Allen of Pasadena, who will make extensive improvements.

At the next quarterly meeting of the Sacramento Valley Development Association the question of federal help for irrigation in the Sacramento valley will be the subject for discussion.

All of the Vail & Gates interest in the Chino Ranch and Town Co., consisting of about 600 acres of farming land, were sold last week to the new company now owning this vast tract.

A fire in the forest between Willets and Sherwood, in Mendocino county, last week, destroyed a lot of timber, besides many cords of four foot wood and several hundred cords of tan bark.

Work on the building of a new box factory was commenced at Anderson this week. Over 3,000,000 feet of lumber is now lying at Cottonwood, to be shipped to Anderson to be worked up.

The assessed valuation of Mendocino county is about $600,000 over last year. The total value of all property being $11,717,000. The footing shows 26,419 head of cows and calves; 97,050 sheep and lambs; 1769 Angora goats.

Another large electric power plant is in the course of erection at Silver Lake, Plumas county. A large dam at the outlet of the lake will cause a storage of many millions of gallons of water which will be used to supply power for the plant.

A tract of eighty acres has been purchased by the Arizona Fair Association near Phoenix for $9000. Great barns, and grand stand capable of seating two thousand people will be erected at once and the first fair will be opened in November.

The California Wine Association will hold a meeting on August 24th for the purpose of voting upon a proposition to create a bonded indebtedness of $2,000,000, the amount to be thus secured to be used to pay off present floating indebtedness.

At the Plant Introductory Garden at Chico, honey plants will be tested, bee diseases on the Pacific Coast will be investigated and other experiments with bees conducted. Among the varieties the Giant bee of India, and various specimens from the Philippines, will be experimented with.

Ensilage as a Dairy Feed

By Mrs. Minna E. Sherman, Fresno, Cal.

(Concluded.)

Good corn ensilage should be amber colored, and the greener feeds a little darker. It should smell like malt extract, and be sweet and slightly sticky. The corn on the rings of cobs tastes like corn fresh from the can, and with a little salt is quite palatable to the taste. In the tonnage produced by the different varieties of corn the difference is marked, and makes it difficult to estimate the actual cost of the ensilage. There are four varieties of corn grown from seed purchased in Chicago, which gives us much better results than the corn seed purchased in California. These are "Reed Yellow" and "Legal Tender" for July sowing, with either "Early Yellow Rose," or "Mortgage Lifter" for April sowing. With these corns we gain nearly a quarter more leafage and more tender, succulent stalks than with the common varieties.

We usually sow corn on the land that has furnished a hay crop and then been irrigated and plowed for corn which is planted in June, or as late as the Fourth of July. The corn is irrigated twice and cultivated enough to keep the weeds down. By the last of September it is ready for the silo. Three months from sowing, it is in the dough stage, so by sowing in succession, leaving ten days between, the entire crop can be put into the silos in exactly perfect condition.

The government, recognizing the great value of the corn plant, and that it was often sown from inferior seed at a loss to the producer, has taken up the study and pedigree of the corn family, and has already found how great is the difference in productiveness between seeds of the same variety from a careful grower and that of the ordinary commercial article. The experiments have also shown the food values to differ somewhat. Some grains with more than the usual amount of hard outsides or cuticle, were richer in protein; that having large grains gave a greater amount of corn oil, while the starchy center which carries the carbo-hydrates, varied even more than the size of the grains would indicate. The size and shape of the grains, their weight in proportion to the size of the cob, and the way the grains filled out the seeds, sometimes made one corn crop double the value of another—grown with the same amount of labor and expense. While there have been pioneers in this field, as yet the varieties or types have not been fixed long enough to be called families or races.

With good seed, we count on twenty to twenty-five acres planted to corn, filling the 318-ton silo. This is allowing also for careless irrigation and scalding. This acreage often furnishes more than the silo will hold, and we cure the surplus for fodder for the colts and stock cattle. The colts like it, and it seems to give them something they need of a woody nature, for they do not eat the fences so badly while the corn fodder lasts.

Sugar-beet pulp is often compared with corn ensilage and is nearly as good for milk making However, as it is not practical to move the dairy cows to the sugar factory, use of the pulp for feed must be left to the raisers of beef cattle.

The flint varieties of corn have nothing to recommend them for the silo, as they produce less leaves and stalks than the dent varieties, and are harder and tougher.

In ten years the number of silos in the United States has doubled and the average production of the cows has kept pace. The annual production of milk per cow has increased from 1400 to 2600 pounds. This is nearly doubling the production or equal to adding that many more cows.

The gain in making the corn into ensilage is in the fact that the cows receive it when at its best, neither too old and tough, nor when immature and green, but when it is best for succulency, palatability and food value.

Lately, the peas and oats we used to grow for silage, have been dropped from the ranch crops and the lands put into alfalfa, the first and last cuttings each season going into the silos, and the three or four summer cuttings made into hay. The first crop of alfalfa is full of fox-tail and bronco grass. To it are also added the grass clipped from the borders of driveways. When young and fresh, there is hardly a richer milk-making grass in California than the hated fox-tail. In the silo the fox-tail and bronco grasses are made tender and the vitality of their seed destroyed. It is a cheaper way to clean hay than discing the alfalfa fields, particularly for the vineyardist, for at the time of year the alfalfa needs discing every man and horse is wanted in the vineyards and orchards. As a matter of expense, it was therefore cheaper for us to silo the first crop than to disc the land; and grow alfalfa than to grow peas and oats.

On land foul with weeds, peas and oats for a winter cover, and corn as a cultivated crop during the summer, will in a few seasons discourage the undesirable growths—even Johnson grass and Morning Glory suffer under this double cropping. If the few spots that survive are marked with a stake and later cut off with a sharp hoe they seldom appear again, and the land is ready to be made into vineyard.

While corn ensilage in dry weather has a food value one-third as great as hay, yet to gain a greater milk flow we do not have to feed double the amount, for while 28 pounds of alfalfa hay with 8 pounds of straw is a ration, 35 pounds of corn ensilage with 8 pounds of alfalfa hay is a much better one for milk making.

Ensilage has as great succulency as green grass and produces a relatively greater flow of milk. It also agrees well with the cows. While the cows are eating the hay and straw ration, they are needing doses of salt and ginger almost daily. Every dose of these depleting medicines is wasting the food of several days' rations, so that at the end of the month, the loss of milk, the price of the salts and the time taken to give the dose, will use the product of one or more cows to compensate.

Ensilage is as near to preserving the natural food for the cows as we can make it; therefore they are healthier and thrive better than on the dried products of hay and grain. To their physical economy it is about the same as canned vegetables and fruits have proven to be to the human family. The matter of ensilage feeding has been discussed fully in the various dairy associations, and the conclusion has been reached that a well fed herd of cows will increase their productiveness from one-third to one-half, when ensilage is made part of the winter rations.

The entire waste of food in a well filled silo should be only the four or five inches of mould that seals the top. It keeps well—so well that we have had ten feet of new ensilage on top, a few feet of two year old, a layer of three year old and in the bottom of the silo the ensilage was four years old. The cows ate it all with as good relish as the fresh, and it seemed sweet and good to us. With us, ensilage has solved the problem of keeping cows on a limited amount of land.

Another soiling crop not half appreciated in California is sorghum. It can be planted at any time there is a lull in the spring or summer work. As soon as it makes a second joint, it can be cut for green feed, and will at once sprout out again; so a limited patch will supply a large amount of green food. It seems to lengthen out the summer feed and fills the time when the pastures have lost their freshness and the winter rains have not yet started the natural grasses.

Sharples TUBULAR CREAM SEPARATORS

WHICH DO YOU WANT?

Tubular or Bucket Bowl?
Simple Bowl or Complicated?
Izzers or Hasbeens?
Waist Low Can or Head High Can?
Self Oiling or Oil Yourself?
Wash 3 Minutes or Wash Thirty?
All the Butter or Most All?
Best Butter or Medium Butter?

Tubulars are different, very different. Just one Tubular—the Sharples. All others make bucket bowls—can't make Tubulars because they are patented. Ask for catalog Q-260.

It serves before we begin with the silage, to give a variety to the sows' food and stimulates appetite.

Sorghum grows readily over a wide range of soils and stands heat and drought. Its adaptability to California is indicated by its natural habitat, coming from the arid countries of Africa and Asia, where the grain is used for the human family, while the dried leaves and stalks are fed to cattle. There are nearly as many varieties of sorghum as there are of Indian corn, but as they have been introduced from different countries under foreign names, they are usually not called sorghum. The two families are the saccharine and the non-saccharine. The improved saccharine varieties are apt to have smaller leaf growth, and are therefore not so valuable for soiling as the older Chinese variety introduced into this country in 1855. This is the parent variety of the Early Amber and has proven to be the best with us.

The Kaffir Corn, a non-saccharine sorghum, has much to recommend it, though it sprouts less readily after cutting, and on sub-irrigated ground, grows so rank that it falls over and has to be cut by hand; though on very dry, sandy land, it will produce more grain than from the Early Amber or Egyptian corn.

The land intended for the sorghum should receive a plentiful irrigation and be well plowed and harrowed. The seed is drilled in rows, using about 35 pounds of seed to the acre. The harrow is run over the field when the sprouts begin to show. Usually two harrowings suffice, though the Early Amber sorghum roots deeply before it makes much top growth. The harrow should be used until the ground is shaded for there is little danger of sunburn even if the land is hard and runs together, though the best crops are raised on the more sandy soils. Sorghum will grow and mature on land having too much alkali for common corn, though of course the light loamy and white ash soils give the greatest tonnage.

When the plant comes into blossom, it is at its best for feeding and can be cut for green feeding or cured into hay. If it is used for hay, we find it has to be hauled off the land on which it is grown for lack of room to cure it. After lying on the ground twenty-four hours it is raked into piles about six feet square. In two or three days it will have sweated and heated and is then spread out again, and when cured —but not dried until brittle—it can be stacked without fear of spoiling.

Sorghum also makes a good sandwich by putting a foot of the green new-cut sorghum between six-inch layers of straw.

The third way of preserving it for winter feeding has been our practice. We cut when the seed is in the dough stage of ripening, hauling it to the place from which we intend to feed it. It is stacked, using the derrick fork and keeping the stack tall rather than broad and low, so that when completed it will be two or three times as high as it is broad. It is tramped on the outer edges and gradually brought to a pointed or ridged top. The regular 16-foot panels of shake roofing used on the hay stacks are placed on it, and old iron—parts of headers from the junk pile—put on the boards to keep them firmly pressed into place. The top of the stack may have a few loads of alfalfa hay put on top if it is not level enough to hold the roofing close to the sorghum. It cures well in this manner, remaining moist and succulent inside the stack and drying into hay on the outside. In using it for hay it is cut from one end, using a hay knife. It is valuable for winter feeding of the yearling heifers and colts on pasture as well as for the cows.

The sorghum field having been cut, now has the furrows plowed out between every row, and if well irrigated and harrowed, sprouts up again. If it was sown early enough, a second cutting may be had for hay, though usually after making one cutting, we cut it out every day and feed it out as a soiling crop.

The sorghum has small roots and the frost cuts it down promptly, and the land is ready to grow barley or wheat as soon as it rains; while Egyptian and Kaffir corn land requires labor to clean—the roots having to be thrown out with a plow and raked up as they never seem to rot, and will seriously interfere with the mowing of the next year's crop of hay if not taken out of the way. We have had them three years piled up before they were dried out enough to burn.

When we plant sorghum in April we can harvest three crops. The first cutting usually yields about five tons to the acre, the second about seven and the third cutting a little lighter; so fifteen tons of sorghum to the acre is a fair crop.

Sorghum must be fed in limited quantities until the cattle grow accustomed to it; otherwise it may cause bloating. It is never safe to use as pasture, for when the stock help themselves they can fill up too quickly. The necessity of beginning with small feeds applies to all the forms of sorghum, whether it is hay, sandwich, or from ensilage stock. Even after they have been eating freely for some time it is well to spread it from the wagon over considerable ground, so the animals have to pick it up in limited mouthfuls. As the amber cane contains a high per cent of carbo-hydrates, it feeds well with alfalfa hay. If that from the ensilage stack is used, fifteen pounds of alfalfa hay with all the sorghum the cows will eat up clean, will give a good yield of milk. If the cows leave the hay, reduce the sorghum until they eat their hay up clean, or they may scour badly and go off their feed.

In our experience with sorghum so far, we have not had any cattle poisoned by it; yet at times it, as well as Kaffir corn, is very deadly to cattle. Dr. Haddon, of the Colorado station, found one per cent of prussic acid in the leaves of Kaffir corn from a field where cattle had died; while Mr. Slade, of the Nebraska station, found in a sample sent him from a field of sorghum that had proven to be poisonous, .014 per cent of the entire weight of the sample to be prussic acid. As the leaves contain most of the poison, the cattle in a field, by rejecting the stems, would receive a greater proportion than the analysis of the plant shows to be present. In case of poisoning not immediately fatal, the remedy is a quart of molasses or a couple of gallons of milk or buttermilk.

Why sorghum should be wholesome most of the time, yet occasionally should form one of the quickest and most deadly of poisons, has not been discovered. Dryness, second crop, excessive moisture, shade, too hot sun, over cultivation, lack of cultivation—have been suggested, but careful investigation and experiments have shown fields of sorghum perfectly wholesome under these conditions, and that the fields that were fatal to cattle had the same cultural and physical conditions as the healthful ones. So while we know what the poison is, the cause for the present must be assigned to the total perversity of inanimate things.

While sorghum is not as valuable as corn, it has a place that would be hard to fill as cheaply with any other feed. The grain alone is worth in feeding value ten per cent. less than corn, though the whole plant has a little greater digestibility than the entire corn plant. Sorghum and corn both need balancing with protein. That, alfalfa furnishes us very cheaply. We can also find it in bran—at a higher price however. Corn has had its poet, when Longfellow sang of its beauty, while alfalfa has only had the cattle men to prosaically say "Its good." Yet nature's bees and birds hum and sing of the alfalfa fields and the cows draw in deeply of its cool, soft air, full of the sweetness of the alfalfa bloom. So alfalfa receives the homage due to the king of all dairy foods produced on the farm.

That which is good feed will make good manure.

LICE ON ANIMALS.

From one of those admirable little bulletins issued by the Kansas Experiment Station some time since, we note the following on control of lice:

"These wingless insects are found parasitic on all animals. Cattle are unfortunate in being the most common victims of lousiness. Sheep are rarely affected. We meet with this disease most frequently during the winter months, in neglected, half-starved, dirty animals. Young animals are especially liable to be infected. Somtimes, however, even well kept cattle suffer severely.

So-called lice are either true lice (Haematophinus) or bird lice (Trichodectes). The former have a slender often spindle-shaped body, a pointed head, grayish blue color, and suck blood. The Trichodectes are broader, have a squareish head, brown color, and have biting mouth parts, living on hair and epidermal scales. Trichodectes are usually found on neglected, unthrifty animals with long, shaggy hair and a dirty, scaly skin. They usually disappear as soon as the animal's condition improves. True lice, on the other hand, occur also on thrifty animals.

Every species of domestic animal has its own specific louse, or lice (horse louse, ox lice, two kinds, pig louse, goat louse, dog louse, etc., and Trichondectes of the horse, ox, sheep and dog). The louse of one species of animal can not exist permanently on another species.

* * *

Symptoms.—Lice always give rise to a troublesome itching, causing the animal to rub and scratch the infested portions of the body. The hair is rubbed off, or drops out, the exposed skin becomes inflamed, scaly, and even covered with extensive eruptions and large, raw, bleeding surfaces, giving the animal an extremely distressful and unsightly appearance.

Lice seem to prefer the region of the neck and mane, the back, root of tail and, in cattle, the base of the horns, in pigs the region between the hind legs.

The presence of lice and their nits attached to the hair is sufficient evidence regarding the nature of the trouble.

* * *

Treatment.—There are many remedies for destroying lice, e. g., arsenic, mercurial ointment, helebore, tobacco decoctions, the seeds of Delphinium staphysagria (staveacre), creolin, carbolic acid, lysol, train or fish oil, etc.

The following are of especial merit.

1. Mercurial ointment, diluted with a little oil, is very effective on horses and pigs. It is applied in small quantities to the affected parts only. It must not be used on cattle.

2. A tobacco decoction (one pound tobacco and three gallons boiling water, allow to stand for half an hour) with or without the addition of two pints of vinegar, is very effective; but often produces nausea in horses and cattle.

3. Five per cent solutions (three teaspoonfuls to a pint) of creolin or lysol, in water containing 20 per cent of alcohol, well rubbed in with a stiff brush, is very effective.

4. The remedy which has given the most satisfactory result to the writer is kerosene emulsion, made as follows: Kerosene, two gallons; common or whale oil soap, one quarter pound; water one gallon. Heat the solution of soap and add it boiling hot to the kerosene; then churn the mixture for ten minutes. Be sure to have the water boiling hot when you add it to the kerosene, and churn it thoroughly, otherwise you will have trouble in making a good emulsion; which, when made right, should have a creamy appearance. Dilute the emulsion with twenty gallons of water and apply with a spray pump. If no spray pump is at hand, drive the animals, if many are to be treated, into a narrow chute and apply the emulsion with a common watering can, being careful to treat all parts of the body.

Select a mild, sunshiny day for the operation. In the course of four days or a week repeat the application in order to destroy those lice that have, in the meantime emerged from the nits. Where the animals have been kept in stables or pens do not neglect to give these places the same treatment; they are just as lousy as the animals, and if not treated they will soon reinfect the animals. Finally, avoid conditions favorable to future infections, by giving animals proper care and keeping them in vigorous, thrifty condition. For long-haired animals (calves), shearing might be recommended. Weak, rundown animals may require special nursing to recover completely from an attack of lousiness."

FLIES FROM CATTLE.

An eastern exchange has the following, which looks anything but attractive, and think it should be tried with caution. It certainly looks as if it would keep flies off:

Take coal tar, two parts, and coal oil and grease, one part, and mix with small amount of carbolic acid. Apply with a cloth by moistening the hair and horns of the animal with the liquid. In the applications include feet and legs, and it will drive every fly away, and one application will last ten days or more in dry weather. Apply as often as necessary and your cows will be entirely free from flies of all kinds. Any kind of old lard or grease can be used. Coal tar is the base of this remedy, and when too thick to spread well use more coal oil; when too thin to adhere well use more coal tar. Carbolic acid will cost about 50 or 60 cents per pound in crystals by the pound, and every farmer should always keep it on hand, as it, in its many uses, is indispensable.

Nothing is so good as the earth floor for animals that have tender feet.

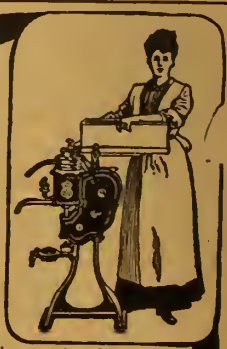
U. S. SEPARATORS SOLD BY K. B. NORSWING
MAIN ST. AND SLAUSON AVE., LOS ANGELES
Separators can be seen at store, near end of Maple avenue car line.
If you contemplate buying a machine let us show why ours is the simplest, easiest running and most lasting.
Separators can also be seen in operation on nearby dairy farms. Correspondence solicited.
When writing advertisers mention Cultivator.

TIME IS THE TEST
of durable construction in a high-speed machine like the cream separator. No other machine a farmer uses has a harder test. Run twice every day, winter and summer, it must not only do thorough work, but to be permanently profitable, it must be durable.



U. S. Cream Separators
Which hold World's Record for Close Skimming,
are built for long service. A solid, low frame encloses entirely all the operating parts, protecting them from dirt and danger of injury. The parts are few, simple and easy to get at, every one being subjected to most thorough inspection, both of material and workmanship. Ball bearings at high speed points, combined with automatic oiling, reduce wear as well as insure the easiest operation. Every machine is tested before shipment. Such careful and thorough construction is what enables the U. S. to better

STAND THE TEST
than any other separator. You don't have to buy a new one every year or two. And remember: the U. S. does the closest skimming all the time.
Read a few of the thousands of letters from people who have used the U. S. 5, 8, 10, 12 or more years. They know about the "test of time." Send for Catalog No. 550. It's free and it's interesting, and will point the way for you to save money as well as to make money in your dairy

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

FORCING THE MOULT.

"Will you kindly explain what is meant by forcing the moult and why and how it is done" writes (Mrs. W. H. Y.) a beginner.

I thought that last week's article covered most of this ground, but perhaps I was not explicit enough for "a beginner" to understand. "Forcing the moult" or "controlling the moult' is making the hens moult at any season or time that you may wish.

The moult is always more or less a trying time to a hen. It usually takes, unassisted, from sixty to a hundred days. Some hens moult quickly and some slowly, according to the condition of the fowl, the season of the year, and the quality of the food.

Egg making food, the food which contains the elements of the egg, is the food which contains the elements of the feather. Feeding is a very nice subject, and can only be determined by experience. If too rich a food is constantly fed it will either induce a continuous moult or will result in indigestion and liver trouble. To feed as highly as possible without over feeding is what we want for both eggs and feathers.

Last year at about this time I gave our readers a synopsis of the experiments with moulting hens at the West Virginia Experiment Station, the year before. Two years ago I described Mr. Henry Van Dreser's method and each season I gave my own trial of forcing the moult. Last week I told you what to do without explaining all my reasons.

I have now before me a very able article from Dr. Sanborn's pen, headed "The Forced Moult, how to do it, the change in feeding, what not to do." His methods are almost exactly what I have already described to you, but I give them again in his words. He is one of the best and most scientific authorities on poultry in this country, his books and writings are standard works. He is associate editor of "The Poultry Keeper" and the article from which I quote is in the July number of that excellent poultry magazine.

* * *

"Today we take our birds and use them as we would a machine. To be sure we handle them carefully, we look to the future as we get the profits of the present. Yet it is true that we are trying to get the most dollars from our poultry farms. One of the helps to large egg profits is the forced moult. It is not enough to wait for the bird to moult when nature would do it. This might be so late in the fall or early winter as to prevent any winter eggs from the yearling hens. If you do not keep over any of the hens that have been laying for the last eight months then the forced moult is not of help to you.

If you do not keep over the best of the yearling hens I think you are making a mistake. These birds that will be two years old the coming spring will make the very best breeders you can find.

* * *

Handling the Old Fowls.—I suggest that you pick out the best half of the females hatched in 1904 and pen them for a forced moult. Let these birds have all the strong points of the variety you keep. Let them show practical points first, fancy second. To have the birds moult so as to begin laying early in November, they should begin to be treated before the first of September. I do not advise starting my plan before the first of August. Suppose we have thirty hens that are the best of last year's hatch. These we have culled out of eighty that have done the bulk of our laying the past eight months. These thirty contain the few birds that observation, or the trap nest, has shown us are our best record egg layers. The market chicks, now half grown, coming from special eggs, help us in the final selection of some of these thirty hens. We wish to save those birds that have been our producers, either of large numbers of eggs, or of show stock.

* * *

Low Feeding, or Starving Process.—These selected birds we will yard where more shade is plentiful, where the ground is covered with grass, and where space is not limited. Until the last of August we will feed these birds moderately, working for a fair egg yield, not stimulating and not underfeeding. Along the latter days of August we will cut out much of the usual food. All corn and corn meal, meat scraps and green bone, are omitted from the daily ration. One meal a day is fed, and that at night. That can be whole oats soaked in hot water for an hour, fed moderately. It may be, several times a week, just a measure of dry bran. One night of each week it can be barley, another wheat, and so on, omitting all corn products. It is largely a question of what not to feed as well as how little to give the birds you desire to moult.

There is one line of foods you may feed in unlimited quantities and that is the green vegetables. The waste, small beets and thinnings of the garden rows, can be supplied every day. If the yard is all bare, the cuttings of the lawn can be given every day. My own plan, in the days when I had small, ungrassed yards, was to give full quantities of lawn clippings, putting them in the yards an hour before dark. This gave the birds time to fill up at night, and yet the uneaten clippings would be still fresh in the early morning.

If you have had no experience in the use of lawn grass, you will be surprised to see the quantity that a few hens will eat. If your hens have very large yards with fruit trees to supply some falling apples or pears, the birds will do very well without any other food. We are inclined to overfeed our birds in warm weather and unless the food is really much less than usual you will fail in getting an early moult.

This low feeding or starving process as it is called by many, is the important factor in the forced moult. Unless you really do this in good shape the birds will continue to lay and shed

HOW 1700 HENS BUILT A $3500 RESIDENCE

Story of a Southern California Poultry Farm

H. D. FREEMAN,
Santa Maria, Cal.

(By A. R. COULSON.)

On our automobile trip to Los Angeles, we found that there were several large poultry farms situated near Santa Maria, about four miles from town. As we were interested in seeing some of these large poultry farms we made a special trip out for that purpose. We first called on Mr. A. J. Freeman, who cordially received us, and made us feel heartily at home, and Mr. Freeman said he would take the afternoon off and show us the richest country in the world. So we took him, his wife and two children, in our machine, and we rode out for several miles to the new oil country, where we saw oil flowing in streams, and there were three large lakes of oil, as smooth as glass, and reflecting like a mirror. Whole lakes of oil, millions of dollars worth, and a little further up the mountains were two large gas wells, which were on fire, and the flames went up hundreds of feet in the air, and could be seen for many miles away, and they had been burning night and day for many months.

* * *

On our way back to the ranch, Mr. Freeman said we would go in and see his brother, Mr. H. D. Freeman, who is recognized as the largest and most successful poultryman of that country. Mr. H. D. Freeman was rather surprised to see us all, but welcomed us cordially.

Mr. Freeman invited us into his new residence, which is an elegant house of fourteen hard-finished rooms, eight closets, and cement cellar floor. His ranch covers 200 acres of good, rich land, and all surrounded with poultry wire netting fence to keep out all wild animals. He keeps 1700 laying hens, and for the past several years has kept books, recording the receipts from poultry, cost of feed, etc., and he showed us the books that showed how MANY MORE EGGS were laid, and how MUCH MORE THE RECEIPTS were the last year SINCE FEEDING COULSON'S FOODS, than they were for two or three years before, from the same number of hens. During the last year, from May 1, 1904, to May 1, 1905, the 1700 hens netted him a profit of over $2000.

* * *

EGG RECORD.

1700 hens fed one year on COULSON'S EGG FOOD. One meal each day. Started April 18, 1904. Eggs increased from 40 to 73 dozen a day.

Mo.	No. eggs.	Doz.	Amt. rec'd for eggs.	Rec'd P'ltry Sold
1904—				
May	23,472	1956	$343.16	$14.80
June	19,464	1622	292.56

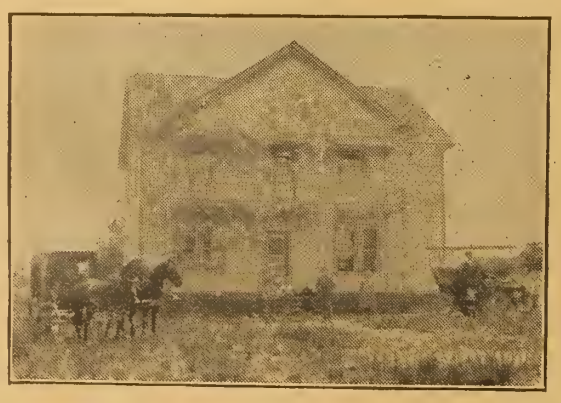
Dec.	11,042	920	319.49	
1905—				
Jan.	15,780	1315	304.40	
Feb.	21,840	1820	324.10	
Mar.	25,040	2087	347.39	
Apr.	23,228	1936	346.61	96.20
	195,970	16,331	$3633.36	$263.20



H. D. Freeman's new residence, 14 rooms, 8 closets and a cement basement; Cost, $3500.00. Built from the profits of 1700 laying hens (in 18 months time) which were fed on Coulson's Egg Food.

NOTE—During the last month, April, hens were only fed one sack a day of the Egg Food.

Amt. rec'd from eggs sold	$3633.36
Amt. rec'd from young roosters, etc	263.20
Value of eggs and poultry used in family	178.20
Total	$4074.76
Value of 510 sacks of Coulson's Egg Food fed	$ 892.50
Value of 577 sacks wheat, barley and corn fed	1115.20
Total cost of feed for year.	$2007.70
Net profit, 1700 laying hens fed one year on Coulson's Egg Food as per careful daily record	$2067.06

Scene on Freeman's ranches near Santa Maria. These fowls are all fed on Coulson's Feeds regularly.

NOTE—The poultry sold was young roosters, etc., fed with above supply of feed.

Figuring the value of wheat, oats and barley, at what they were worth if he was to sell it, as he raised his own grain (about 150 acres), his profits are really much more than as above stated, for raising his own feed, he did not have to buy much more than 510 sacks of Egg Food. He fed them 1½ sacks a day of it, excepting during the months of March and April last, he used but one sack a day and the hens averaged over two cases of eggs a day during these months. From now on, June 1st, he feeds them 1½ sacks a day for the morning meal.

During the past year he has put up fifteen new poultry houses, and also built a $3500 residence, which he moved into on April 25th. As the poultry has proved so profitable when fed on Coulson's Foods, this year he is raising several thousand more (they are fed on Coulson's Chick Foods), so that by fall he will probably have over 3000 laying hens.

Mr. Freeman's brother, Mr. A. J. Freeman, also has about 1000 laying

Freeman's White Leghorn Poultry Farm

Santa Maria, Cal. May 20, 1905

Coulson Poultry & Stock Food Co.,
Petaluma, Cal.

Gentlemen:-

One of your salesmen was through here a year ago and I promised him I would feed Coulson's Egg Food for one year and keep a careful record of results and compare with former years. So I bought five tons of it to begin with, and on April 18, 1904, started to feed one and a half sacks a day of it, as the morning mash. At that time I was getting about 40 dozen eggs a day, but after I had fed it for ten days the hens began to increase, and by May 10th was getting as high as 73 dozen a day. During July, August and September they averaged from 25 to 40 dozen a day, whereas in former years, without your Food they would lay but very few eggs during the molting season, one or two dozen a day being their average.

The record also shows for the months of October, November and December an increase of from 40 to 150 eggs per day over the previous year, with the same number of hens.

From May, 1904 to May, 1905, the 1700 hens have netted me more than $2,000.00 profits. I have put up fifteen new poultry houses and also built a new fourteen-room residence, into which I moved Apr. 25th. So you can see I have found it very profitable indeed, to feed your Egg Food, and I am now glad to place with you another order, this time for a carload of 15 tons, 330 sacks. My brother, A. L. Freeman and my neighbors Eames and Chaffin will take some of this car, so in a couple of months we will need another carload. The feed is all right.

Yours very truly,

H. D. Freeman

Profit for month $140.10

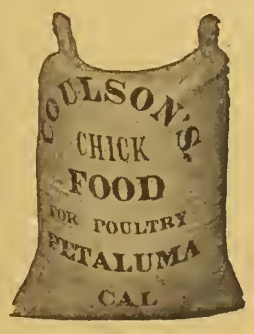
hens, and he is now raising several thousand more little chicks on Coulson's Special Chick Food, so that by next winter he will have a much larger flock. He has also kept a record of amounts received from eggs sold for the past eight years, and SINCE FEEDING COULSON'S EGG FOOD, in comparison to the number of hens, THE PROFITS HAVE BEEN MUCH LARGER. His receipts from eggs sold show the same excellent results.

Mr. Eames, who has a ranch adjoining their farm, keeps a flock of 800 laying hens. He also has fed Coulson's Egg Food for one year, and has kept a record showing the increase over previous years.

Also Mr. Chaffin, another neighbor, has 600 hens, and has fed Coulson's Egg Food for more than a year, with marked increased profits from its use.

A 15-ton car of Coulson's Egg Food was shipped to H. D. Freeman on May 22d, and will be divided among these poultrymen, so that they use a carload of Coulson's Egg Food every two or three months.

For every dollar that you invest in Coulson's Egg Food, you will get back $3.00 worth of eggs. For every dollar ($) that you invest in Coulson's Egg Food, you should make $2.00 profit.



A. J. FREEMAN,
Santa Maria, Cal.

Early morning scene on the Freeman ranch. Feeding Coulson's Egg Food.

it. Hundreds of poultrymen are making it and so can you.

Those who are using $500 worth a year of Coulson's Egg Food are making in return more than $200 a year profit.

So remember that if you feed your fowls Coulson's Egg Food, the year round, that for every dollar ($) you invest in the food, you can make $2.00 profit in return, according to what others are doing.

Stay with the Coulson Food—feed it to your hens right along every day, for there is no better feed made.

You can buy Coulson's Egg Food and Coulson's Chick Foods from most any feed store; or if not, write to factory, give us name of your dealer, and we will send you a free Poultry Account book, as well as fectory prices of Coulson's Foods.

Beware of imitations.

730-732-734-736 MAIN STREET (INCORPORATED. CAPITAL STOCK $100,000) PETALUMA, CAL

GERMAIN SEED CO., Southern Distributing Agents, 326-330 South Main Street, Los Angeles, Cal.

their feathers in the middle autumn.

Handle these selected birds when on the roost. You must feed as directed for weeks, enough to get the birds free from all fat. They must be very thin in body, yet fairly good in color of comb and wattles. I find that my birds take from fourteen to twenty days to get real thin. You will notice, as you put this plan into practice, that the egg yield will drop off until no eggs are being laid; that the birds are on the run all day long, coming to meet you at any point of the fence that you may approach. The birds will show that they miss some of the usual food. This thinning will do no mischief to the birds, in fact I think it adds to the health of the birds for months to come.

* * *

Radical Change in Feeding.—When the birds have lost all spare flesh. when the eggs have ceased to appear for a week, then you change your plan of feeding. Instead of slightly starving the birds you feed them good full rations of slightly growing foods. Now is when you add meat meal, meat scraps, green bone, corn meal and linseed meal. Give them a morning mash of corn meal, two parts; bran three parts; meat scraps one part. Mix this with cool water and feed at once, giving what the birds will eat in a quarter of an hour. At noon feed a small handful of wheat or barley to every bird, and at night a full feed of wheat or corn.

Do not neglect to furnish full supplies of greens and vegetables all the fall.

(To be continued next week.)

* * *

EDITOR'S QUESTION BOX.

Geese.—(B. G. J., Mecca.) Six months ago I was asking you about advice in pigeon raising. I followed your directions and am very much satisfied. I have now again some questions to ask, and will thank you very much for your advice.

I have about ten acres in alfalfa and intend to pasture it off for the benefit of the soil rather than selling the hay. Do you think geese would be a good fowl to raise under the circumstances? Turkeys will of course bring a higher price, but then I have not the range and cannot give them the same attention that they ought to have. Which bird eats more in proportion to meat produced, the goose or the turkey? Which is the most destructive to the pasture it is on? How high would I have to fence in order to prevent geese from leaving the place? What would be the most preferable breed?

In this part of the desert Indian Runner ducks have been quite a success. Could the latter make three-fourths of their living off alfalfa, so that a man would only have to supply one-fourth in grain and animal feed matter?

Answer.—In reply to yours, I am glad to hear that your pigeons have proved a success. I think that you will find geese more satisfactory than any other fowl for your purpose. They graze about as closely as sheep, they do not peck or pull like chickens, ducks or turkeys. They would need nothing but the alfalfa except a little corn at breeding time to call them up to the house or enclosure so as to keep them nearby in safety, and to find their eggs. They are the easiest to raise of any fowl. They are a grazing bird, cutting off the grass as if their bills are a pair of shears. I have two now grazing on our lawn, cutting it like a lawn mower. Turkeys would eat more grain than geese and geese would eat more grass, or alfalfa, than turkeys. I think geese will be less destructive to pasture than any other fowl. I do not think you will have to fence at all to keep geese in; if you drive them off your garden a few times they are quick to learn, besides they are so fond of alfalfa that I doubt if they will leave it for your garden. The only trouble might be in protecting them from wild animals. The Toulouse are the most popular and the most profitable kind. Geese are even easier to raise than Indian Runners. The latter would easily make three-fourths of their living off alfalfa, but to do well they require animal food of some description, frogs, fish, etc. Geese do not seem to need the animal food, but when preparing them for market they should for about two or three weeks have corn to fatten them.

* * *

Cottonseed Meal, etc.—(H. E. B.) Will you be so very kind as to advise me in what proportion to feed cottonseed meal in a mash composed as follows: Three parts bran, three parts rolled barley, one feed meal, one rolled oats, one meat scraps, and one-half part granulated bone. I feed this in the morning to hens and chickens older than three weeks. Do you think it is a too strong meat ration for the chicks? Also, will the addition of cottonseed meal be beneficial? I feed green alfalfa at noon and grain in the evening.

Answer.—Your mash is a good one. The lack in it is green food. Add to it three parts of alfalfa meal; this is alfalfa ground very fine, Cottonseed meal is fattening, is often added to the mash during the last week of fattening to give the yellow color to the skin. It is of very high protein content. The bulletin No. 164 (Berkeley, Cal.) gives it as 47.25 per cent, therefore it must be used very cautiously or it will be too strong and one-tenth of a part is all I would advise you to give. You will find the alfalfa meal an excellent addition but add it gradually, begin with only a tablespoonful or not over one-tenth of the mash and gradually increase very slowly till you are giving taree parts of the alfalfa to the ten parts of other ingredients. Cottonseed meal is a great help in hastening the moult but must be given cautiously or it will upset the digestion and take away the appetite, and you may have to omit one or two meals entirely. Also, if you have white fowls, feed cottonseed meal sparingly as I think if it will give the rich yellow to the skin it may tinge the feathers also with a cream or yellow color which we do not desire. This is only a suggestion of mine. I have fed it, but always carefully and therefore have had only good results.

Trophy Winners at 1903 Los Angeles Show

In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.

My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

Queries and Suggestions

WIRE WORMS.

Editor Cultivator: I send you, by other package, specimens of wire worms. I think that is what they are commonly called. At any rate, they are doing much damage to my place. I plowed under barley stubble, irrigated and planted sweet corn and some other crops and after corn was some three or four inches high, worms commenced on it until now there is but little left. The tomatoes are badly infested and not growing at all and upon pulling them up, find the stem under ground is badly infested. How may I treat them?—E. C., Santa Ana.

About the only treatment for such worms, and we question whether it could be of any value to you at this late stage, is the use of ashes and lime, or the mineral fertilizers, well worked into the ground. Of course, a sure cure is bi-sulphide of carbon placed in holes in the ground. But this, for a good-sized field, of course is out of the question, on account of expense. The only remedy we have seen in a large way is rotation of crops, killing out one year by planting crops which will not maintain the worms, that the crops which these pests infest may be free the next year, although another remedy often recommended and certainly harmless and not expensive to try is the use of tobacco dust. It is much used in truck growing and one authority says it is altogether too little appreciated. It adds some fertility to the soil, so it is not all loss, even if it should prove of no insecticidal value. One authority says it is worth practically all it costs as a fertilizer. This is put into the soil with a common seed drill, drilling well down, when the irrigating water later may carry it down so that it will destroy the soil infesting worms. It is used usually at the rate of 400 pounds per acre, but we imagine this would be too late with your present crops. At best, the wire worm is a most perplexing trial to gardeners and the remedy which will always prove effective will be hailed with delight by many.

CONCRETE HOUSE.

Editor Cultivator: Having abundance of sand on our farm and wanting to build a concrete dairyhouse, I ask how to mix material for building walls of concrete.—Reader, Corona.

In another column of this paper are a few notes on the building of cement floors for stables which give the formula for mixing, but "Reader" must bear in mind that concrete is not a question of sand so much as it is of gravel. Good, clean, sharp gravel, six or seven parts to one of Portland cement is about the proportion usually used for mixing. The cement and gravel are thoroughly shovelled and mixed together while wet and then while shovelling sprinkle over the mixture until all parts are thoroughly wetted, being careful not to mix more than will be used within a short time. It is dumped into the forms which are built up the same distance apart as the wall is to be thick, and kept from spreading under the pressure of the tamping of the cement by heavy wire holding together, which may remain in the wall when the forms are taken away. When dumped in these forms, to the depth of say six or eight inches, the concrete is all to be tamped down thoroughly solid and firm. The article referred to, on cement floors, may be found on page 81 of this issue and will contain additional information along this line.

WHAT TO PLANT.

Editor Cultivator: What fruits or nuts do you advise planting in the sand hills north of Corona? Water secured for irrigation by pumping. Alfalfa grows beautifully.—Reader, Corona.

This question is far better answered by orchards which are already doing well in that vicinity. You mention alfalfa as doing beautifully and alfalfa certainly is a most profitable crop to grow. However, if you wish fruit or nuts, English walnuts usually do well on any land which is favorable to alfalfa. If canneries are convenient it is possible peaches would prove profitable on such land as you mention.

LAND UNDER RECLAMATION.

Editor Cultivator: I am interested in the reclamation projects and would like a little information concerning them. Where are the lands to be opened, how, when and at what cost- Are these lands now withdrawn from homestead entry? If you can not give me this information, can you tell me where I can find out all about it?—G. S., Whittier.

We assume the inquirer wishes to know about the reclamation of the arid land, although it is possible he wishes to know about the reclamation of swamp lands. The latter is a State proposition, and nothing with which the national government has to do, and excepting in a section along the lower Sacramento and San Joaquin rivers is of little interest to California.

The reclamation of arid lands which is being conducted under the Department of the Interior under the act approved June 17, 1902, is probably what our inquirer wishes to know about. First we may say that the best information can be secured by writing to the land office of the district in which land may be wished. For instance, if in Southern California, write to the U. S. Land Office, Los Angeles, California, when a circular of instructions relative to entries on lands withdrawn for the construction of irrigation work for the reclamation of arid lands will be forwarded and such other information as may be desired. In Southern California there is but one district which has been reserved for this purpose, and this in the Colorado desert above Yuma, where the government recently let the contract for a diversion dam at a cost of nearly $1,000,000. These lands have been reserved from homestead entry and may not be filed upon at this time. At what date they will be thrown open is yet unknown. There are projects under way in nearly every arid State, though those in California are in connection with either Oregon, Nevada or Arizona. There are several in Arizona, several in Nevada, also in Oregon and one in Washington. The estimate as to what the cost of the land is to be can not be given, as it will vary in the various districts.

UNDUE HEAT.

Under the head of "False Impressions," the Imperial Standard refers to the Cultivator's recent item of the control of the Southern Pacific over the affairs of the California Development Co., and accuses us of being "intentional prevaricators, because of lack of understanding." Of course we are sorry, and had we known better we would not have been guilty of lying "intentionally."

But why the heat of the Standard we cannot understand. We referred to the recent deal as "the transfer of the principal holdings from former President Heber to the Southern Pacific Co.," etc., and the Standard says the Cultivator "proclaims the Southern Pacific Company as OWNER of the principal holdings of the "Imperial Development Co.,' (Californit Develoopment Co.)

"For the information of the esteemed 'Cultivator' it may be said that:

"The Southern Pacific DOES NOT [the caps are from the Standard] own a single share of stock or bonds of the California Development Co."

Now, as to the actual ownership of the company, it is a mighty small affair. As to whether the Southern Pacific "owns" the California Development Co., controls it under trust deed, mortgage, or what not, is of no general interest. But it is of great interest to the Cultivator and to all its readers, and especially so to people of Imperial Valley to know that somebody, or bodies, with abundance of funds and business sense is to put brainy men in charge and assure the future greatness of that magnificent water system and valley.

The Standard had better save its energy in defending somebody's pride in still being "owner," and use it in showing the wonderful productiveness of that soil when the Colorado river is poured out upon it. That this will be done successfully under the present management we believe.

ANOTHER EXPERIMENT STATION DISCONTINUED.

Reference was made last week to the fact that the State University authorities were about to discontinue the experiment station at Tulare and we now note in the Pomona Times a statement that the Southern California station, located at Pomona, is also to be discontinued. This is occasioned partly at least by the fact that the new pathological station, provided for at the last session of the legislature, will investigate certain diseases and the condition of fruit culture in Southern California, separate and apart from this experiment station. It is perhaps true that the management has labored under the disadvantage of insufficient funds to carry the three experiment stations, but the producers in the various sections who realize the vast diversity of interests in the State and the distance away of some sections from the central station at Berkeley, have felt a need for these experiments to be carried on in their own neighborhood, so far as possible. But nearly all have admitted that in the past results have not been accomplished which they had hoped would be by these various stations. There is probably no State in the Union which gives so varied a list of problems to its experts to handle as does the State of California. Almost every fruit or agricultural production under the sun are produced here and the determination of the best methods of growth under the diversified conditions which exist in this State has been a grave problem. The regents anticipate ability to accomplish more by centering all the work in the central station located at Berkeley and, if that is to be the decision, we certainly hope better results will be accomplished than have been in the past.

The more litter in the manure the shorter the process of decomposition.

MEALFALFA
Reg. U. S. Patent Office
FOR POULTRY
MEALFALFA is very rich in protein (the egg forming element) and also has a good percentage of food element. It is dry and should be moistened with either hot or cold water when fed; this brings out the rich green color, more nearly representing grass conditions; the quality which poultry men are looking for in their feeds. Feed your hens ***Mealfalfa*** and you will find that they will lay very fertile eggs which produce strong, vigorous and hardy chicks; also they will moult quicker in the fall and commence to lay earlier in the season.
For laying hens, we put several quarts of ***Mealfalfa*** into a closed vessel, then pour boiling water over it, until it is thoroughly moistened; place a cover over the vessel and let the mixture steep awhile; just before feeding put a little cold water over the same. Some prefer to mix the meal with table scraps or grain, both of which add palatability and variety to the mash.
For young chicks, feed it mixed with grain or bread crumbs; on this feed they will grow very fast, keep hardy and strong and feather out quickly. Never allow portions of the moistened food to remain in the trough after the chicks have eaten, for any food after being moistened is liable to fermentation.
Stockton Mealfalfa Co.

QUEER SOLOMON OAKS.

A queer old fellow is Solomon Oaks;
He belongs to the good-natured order of folks;
He sings and he whistles about the work
That nobody ever has known him to shirk.
And he makes you think with his blithe good cheer,
Of the merry blackbirds when spring is here.

If they come to him with a doleful tale
Of a neighbor's faults, they always fail
To rouse attention to what they tell.
At such a time he can't hear very well;
But if they praise up a neighbor—then
He can hear as well as the best of men.

He always indorses the good things said
By his friends of the living as well as the dead.
If he's asked what he thinks of a man gone wrong,
He'll pause, perhaps, in his cheerful song,
And say: "I'm sorry, but there must be
Some good to his credit, it seems to me."

"I haven't time to keep track," says he,
"Of the sad things and bad things that I might see
If I was to look for them; so I try
To shut my eyes as I pass them by.
And see only good things along the way—
And I find a lot of them every day.

"By always having something to do
I keep out of trouble and mischief, too.
I stick to my business, as best I can.
And keep on good terms with my fellowman—
And the better I treat him, it seems to me,
The better my fellowman treats me."

A queer old fellow, this Solomon Oaks,
With his merry laugh and his pleasant jokes,
And his faith in his fellows, said or sung,
He's a host of friends among old and young.
He makes them and keeps them by smile and song,
And the word that helps us when things go wrong.

His life holds a lesson 'twere well to learn:
Shut your eyes to the bad; all the good discern;
Keep busy; be cheerful; and aim to make
This old world better for love's sweet sake.
Queer? Well, it may be; this, this I say:
More of such queerness we need today.

—N. Y. Tribune.

A Loss and a Gain

He stared at her across the aisle of the street car. Yes, she was lovely. Perhaps another would not have thought so, for she was imperfect in feature; but she had a sensitive, translucent face, through which shone the light of countless beautiful thoughts. He stared at her intently, till he began to hear her thoughts. At that he came to himself with a start and abruptly looked away.

He had this one strange faculty—that whenever his eyes rested on anyone he at once knew that person's thoughts. It could scarcely be called hearing, though we shall call it so for convenience; it was more a supersensitiveness of all the senses—what people call nowadays telepathy. His mother had always been absorbed in study of the occult, and she had marked him with this power.

He fixed his eyes on the advertisements above her head, and strove to take an interest in them; but he felt her eyes on his face, and though he struggled against it, his glance drew down until it rested upon her. Instantly he knew her thought. "Poor thing," she was thinking, "he looks very sad, as sad as if he knew all the sin and sorrow and fret in the world." He thrilled at the swift, sure diagnosis. "And yet his face is gentle, filled with infinite compassion for it all." At this he smiled a little humorously, tenderly, and their eyes met. For a second the world stood still about the two, as their glances flashed together. Then coolly, without hesitation, the man stepped across the aisle and took the seat beside her.

"Really, I had almost given up hoping to meet you again, Miss—he caught the name from her thoughts and uttered it before she could speak—Marshall. This is more pleasant than I can tell you. But it is so long since the last time we met that you will be quite excusable if you have forgotten me."

"Indeed I have not. Let me introduce you to my mother," she replied with admirable presence of mind, turning to the lady beside her, whom he had not observed before. "Mother, let me introduce you to Mr. Spencer."

He started and looked at her keenly, for she had guessed his name correctly. Was it possible that she too———? No for he heard amid the whirl of her thought: "I flatter myself that I can lie neatly when the occasion demands." So, then, it was only one of the thousand odd coincidences that he was constantly meeting.

There followed a few moments of civil chat with the mother. Then the girl turned to Spencer, and said carelessly, in a low voice: "I'm afraid you must tell me where it was that you saw me last. Unfortunately, my memory needs refreshing."

"Don't you remember, Princess, the many days I spent in your father's palace, while we played his favorite game, chess, and the evenings with you, when——, How is the king, your father?"

"The king, my father is well," she answered with a lift of the eyebrows and a smile, half puzzled, half amused. "And chess is still his favorite game. Mother," turning quickly, "Mr. Spencer here is an expert chess player. He has played for thousands of years," another smile. "You remember how father was longing for someone his equal in skill? Mr. Spencer, it seems, has played with him more than once before."

"Indeed? Then you will come some evening to play with him again, won't you? He has been getting quite restless for an opponent. You will be doing a kindness to him if you come. I assure you, you will be very welcome, not only——. Oh, Amy, here is our street. Goodby, Mr. Spencer."

The girl rose gracefully, poising in the swaying car. "Goodby, Mr. Spencer. You will come?"

"Oh, I shall be very glad to," he replied, ill suppressing his eagerness. His eyes dwelt on her face as she left the car, and so unintentionally he heard her thought—a lilt of glee, with the refrain, "He will come! He will come!"

In less than a week he went to pay the promised call. He sent up his card and the maid came back with the reply that Miss Marshall was out, but that her mother and father were in. Despite the fact that he was sore with disappointment he spent a very pleasant evening with Mr. and Mrs. Marshall, chatting with the one and playing chess with the other. Mr. Marshall he found a most formidable opponent, so much so that several times he was tempted to read his motives from his face, but refrained, for he had long ago decided that that was dishonorable.

He called a second time, and again the mother said that Amy was out, and again he smothered his disappointment and spent a tolerably pleasant evening over the chess board.

A third time she was out also, and he vowed he would not go again. Yet he went a fourth time, drawn irresistibly by his longing to see her. As was his custom now, he went up to the big library unannounced. He paused at the entrance, then drew a deep breath at the lovely picture before him. The library was lighted only by the fire in the great hearth. In front of it, lounging in a big chair, sat Amy, deep in reverie, one hand propping the head with its masses of gleaming hair, the other hanging languidly over the arm of the chair. From where he stood he could see her face clearly in the flush of the firelight, and watching motionless he heard her thoughts: "How I wish I might see him, but how I fear to That day in the car he called me princess—a pretty conceit."

In one stride he was beside her, pressing the languid little hand to his lips.

"Princess, my princess, why are you afraid of me?"

For an instant she lay there motionless, without surprise, for he had fitted into her dream so that she thought she was still dreaming. Then like a flash she sprang away from him and gathered herself for flight, but he caught her and turned her face to the firelight.

"Why are you afraid of me?" he demanded once more.

"Let me go," she cried, struggling. "I am afraid. I was home these three times, but I was afraid to see you."

"Why?" he asked once more, and this time the word was a command.

"Because you can read my thoughts. Because you know my brain and heart and I——." Her voice stopped, but she could not help finishing the sentence in her mind.

"Say it aloud, darling, say it aloud." he cried, half pleading, half commanding. And so, against her will, she must perforce say it aloud, blushing, stammering and ashamed."

He caught her to him and kissed her once. Then once more he turned her face and gazed into it long and earnestly, though she strove to turn her head away and her hands fluttered pleadingly at his breast. Then suddenly a glad light shone out on his face, and she sank down into the chair beside him.

HELP!

Settle Your Own Country

The Santa Fe is doing its share in trying to send more farmers to your country. You can help that work by a little effort.

Every reader of this notice is requested to send to the undersigned a list of his friends in the East who may possibly be interested. Literature regarding your country will be mailed to them, and any questions they ask will be fully answered.

Send list this week to

WILLIAM NICHOLSON,
General Colonization Agent, A.T.& S.F.Ry
Railway Exchange, Chicago

"It has gone," he cried; "it has gone. Thank God! You need never fear me any more. I could never look frankly into the faces of my friends without having their thoughts thrust upon me. I have borne the burdens of a hundred men because of this terrible power. I have grown old before my time. But now your love has freed me from this curse. I shall grow young again."

There was a June wedding in the Marshall family by which old Mr. Marshall acquired a son-in-law, a skillful chess player who could gaze steadily at him between moves without dishonor.—Boston Post.

Cookery Recipes

CUCUMBER PICKLES.

Editor Cultivator: Will you or any reader of the Cultivator kindly give us information how to put up small cucumber pickles? We have tried several ways but have failed to keep them crisp.—L. P. L., Pasadena.

We give below two recipes, both of which are said to be excellent, one somewhat complicated, and the other very simple and are promised another that has worked perfectly with one of the Cultivator housekeepers for many years, but which we will not be able to give until next week.

* * *

Cucumber Pickles.—Cover the bottom of the cask with common salt; gather the cucumbers every other day, early in the morning or late in the evening, as it does not injure the vines so much then as in the heat of the day; cut the cucumbers with a short piece of the stem on, carefully laying them in a basket or pail so as not to bruise; pour cold water over and rinse, being careful not to rub off the little black briars, or in any way bruise them, as that is the secret of keeping them perfectly sound and good for any length of time. Lay them in a cask, three or four inches deep, cover with salt, and repeat the operation until all are in; pour in some water with the first layer—after this the salt will make sufficient brine. Now spread a cloth over them, then a board with a stone on it. When a new supply of cucumbers is to be added, remove stone, board and cloth, wash them very clean, and wipe every particle of scum from the top of the pickles and the sides of the cask; throw away any soft ones, as they will spoil the rest; now put in the fresh cucumbers, layer by layer, with salt to cover each layer. When cask is nearly full, cover with salt, tuck cloth closely around the edges, placing the board and weight on top; cover cask closely, and the pickles will be perfect for two or three years.

Cucumbers must always be put in the salt as soon as picked from the vines, for if they lie a day or so they will not keep. Do not be alarmed at the heavy scum that rises on them, but be careful to wash off the board and cloth.

When wanted for pickling, take off weight and board, carefully lift cloth with scum on it, wash stone, board and cloth clean, and wipe all scum off the cucumbers and sides of cask, take out as many as wanted, return the cloth, board and weight and cover closely. Place the cucumbers in a vessel large enough to hold two or three times as much water as there are pickles, cover with cold water (some use hot), change the water each day for three days. Place the porcelain kettle on the fire, fill half full of vinegar (if vinegar is very strong add half water). Fill nearly full of cucumbers, the largest first and then the smaller ones, put in a lump of alum the size of a nutmeg, let come to a boil, stirring with a wire or wooden spoon so as not to cut the cucumbers; after boiling one minute, take out, place in a stone jar, and continue until all are scalded, then pour over them cold vinegar. In two or three days, if the pickles are too salt, turn off the vinegar and put on fresh, add a pint of brown sugar to each two gallons pickles, a pod or two of red pepper, a very few cloves, and some pieces of horseradish. The horseradish prevents a white scum from rising.

* * *

In addition, here is another, much simpler in manner of handling, and, while it probably will not keep the pickles so long as the above, yet may be of value to our inquirer.

Cucumber Pickles.—Leave a small stem on each cucumber. Place them in brine that will bear an egg, for twenty-four hours. Heat enough vinegar to cover the cucumbers. Heat them a few at a time in the vinegar, pack in a jar and pour the boiling vinegar over them. These will keep for months.

* * *

May we ask Cultivator housewives to favor us with tried recipes along the pickle line? This is the season of the year when they will be of value and if we can make a symposium on pickles a few weeks later, it will be appreciated. Let Cultivator housewives send in their recipes.

* * *

MARSHMALLOWS.

Editor Cultivator: Will you kindly favor me with a recipe for marshmallow filling for cake, also one for candy such as is sold by confectioners?—S. H. M., El Cajon.

Unfortunately, we are unable to get a formula for the making of the paste without using the marshmallow confection as a foundation, though we are positive there are other and possibly better recipes than the following. It is possible that we may secure them by another week but, in any case we ask Cultivator readers who may have a good marshmallow recipe to send in. However, we give this week two marshmallow cake recipes and the following recipe for the making of marshmallow candy, which may answer the purpose of the inquirer.

* * *

Marshmallow Cake.—Take any favorite recipe for cake and make two good layers, putting one in the oven before the other; flavor them with lemon.

Use banana marshmallows, if you can get them. Have them a little warm and place them as close as you can crowd them on the first layer of cake. Try to have the other layer just ready, so it will go together hot. Make a lemon icing of the white of one egg, same quantity of lemon juice and sufficient confectioner's sugar to make it the proper consistency.

This cake is better to stand a day or two before eating.

* * *

Marshmallow Paste.—Three-fourths cup sugar, one-fourth cup milk, one-half teaspoon vanilla; one-fourth pound marshmallows; two tablespoons hot water.

Stir milk and sugar together and boil without stirring for six minutes—counting the time from the moment it begins to boil all over the surface. Melt the marshmallows, and add two tablespoons of hot water, cooking over hot water until smooth, stirring meanwhile. Combine the two mixtures, and beat until stiff enough to spread. Add the vanilla last. If the sugar is stirred while boiling, it is apt to granulate.

* * *

The following is recommended for the confection:

Marshmallows.—Dissolve, by heating over a slow fire, eight ounces gum arabic in three gills water; stir and strain. Boil one ounce marshmallow roots in a little water for half an hour slowly. Add the gum solution with a half pound of loaf or powdered sugar; let cook slowly and stir constantly until it becomes a thick paste which will roll between the fingers. Add the well beaten whites of two eggs, stir for a minute or two and pour into a pan to cool. Sheets of white paper should be placed in the bottom of the pan with the ends projecting in order to lift out the paste, when it may be cut into little blocks and rolled in powdered sugar.

* * *

PICKLED LIMES.

Editor Cultivator: Will you kindly give me formula for pickling limes?—H., Pasadena.

So far we have been unable to find any such formula as asked and will ask the family of Cultivator readers to aid our inquirer with such recipe.

HOMELY HINTS.

Striped wall coverings are always effective in low studded rooms, as they seem to give height to the side walls.

Keep an oyster shell in your teakettle and it will attract to itself the earthy particles which would otherwise form a crust on the inside of the kettle.

After the juice has been squeezed from a lemon the peel and pulp should be saved for cleaning brasses. Dip the lemon first in milk and then in brick-dust and rub it well on to the tarnished brass.

Someone has said that hardwood or stained floors are more easily kept clean than a carpeted floor. This is not true. It is true, however, that it is harder to leave a hardwood floor unswept, because every particle of dust shows on a polished floor, and it must be swept daily. So it is usually cleaner than the carpet. To sweep a wood floor pin over the broom a clean crash cloth, slightly damp, having been wet and wrung dry. Sweep carefully and change the position of the cloth as it becomes dirty. Wash it before using again.

To get rid of the smell in a room newly painted place a vessel full of lighted charcoal in the middle of the room and throw on it two or three handfuls of juniper berries. Shut the windows, the chimney and the door. Twenty-four hours afterward the room may be opened, when it will be found that the sickly unwholesome smell will be entirely gone. The smoke of the juniper berry possesses this advantage, that should anything be left in the room, such as tapestry, etc., it will not be spoiled.

LITTLE HELPS BY THE WAY.

What's the use of worrying,
Of hurrying
And scurrying,
Everybody flurrying
And breaking up their rest,
When everything is teaching us,
Preaching and beseeching us,
To settle down and end the fuss,
For quiet ways are best?
The rains that trickle down in showers
A blessing bring to thirsty flowers,
And gentle zephyrs gather up
Sweet fragrance from each brimming cup,
There's ruin in the tempest's path,
There's ruin in the voice of wrath,
And they alone are blest
Who early learn to dominate
Themselves, their violence abate,
And prove by their serene estate
That quiet ways are best.
—Josephine Pollard.

VERY ACCOMMODATING.

Brakeman—"Now, then miss, get in quickly, please. The train is about to start."

Young Lady.—"But I want to give my sister a kiss."

Brakeman—Get in! Get in! I'll attend to that for you."—Exchange.

A DEFINITION.

"What is luck, mamma?" asked small Floramay.

"Luck, my dear," replied her mother, " is what a man trusts to when he can't trust himself."

THE STAR OIL BURNER
ITS OWN GAS MAKER
(Patentees N. L. Rigby and S. S. Sprague
This Burner is offered to the public upon its merits. It is not an experiment, but a practically tested and successful invention. It has no superior for safety, simplicity, economy and durability. It is made without bolts, screws or rivets. It makes a pure dydro-carbon gas from low grade distillate oils, and gives you a fire as bright as the stars. Free from soot and smoke.

THE STAR BURNER.

A good oil burner, one which makes but little smoke and one which is reliable, is a jewel in this country, where other fuel is high priced and where oil is low priced. None of these burners have been manufactured yet which are absolutely perfect, but the later inventions have been vast improvements over the old timers. One of these which is proving a most satisfactory burner—one of the very best—is the "Star," manufactured in Los Angeles. We saw one burning in an ordinary cook stove the other day, and will say that it is certainly a clean-burning, heat-producing and economical burner. There is almost no smoke, none could be seen coming from the chimney, and the ease with which it is started and operated is remarkable. The manufacturers, Messrs. N. L. Rigby and S. S. Sprague, say regarding its good points: A saving of 25 to 40 per cent over wood or coal, and over gas if you accomplish as much. A clean, bright fire, with an even, uniform heat at any required temperature. No poisonous vapors from the stove, and no more smoke or soot than from a wood fire.

HOEGEE'S HANDSOME HAMMOCKS

Hoegee says he has sold a "raft of hammocks" this season and in order to clean out quickly will sell the remainder at a third off. Drop a card to him and get further information, for you can take advantage of the liberal discount and order by mail.

Nothing is nicer under the trees or on the porch than one of Hoegee's hammocks.

OF INTEREST TO PURCHASERS OF FERTILIZERS.

Mr. A. C. Pickett, of Riverside, has been appointed deputy inspector of fertilizers for Southern California by the Director of the Agricultural Experiment Station of the University of California. Mr. Pickett will be on duty throughout the year, and will sample not only fertilizers in agents' warehouses, but will sample shipments made direct to the purchaser if notified by the purchaser of the arrival of the goods, and if the lot is large enough to justify the trip. All samples collected by Mr. Pickett will be forwarded to the Experiment Station at Berkeley, and will be analyzed in the order received. Any farmer desiring an immediate report of an analysis of a sample of his goods may obtain same by taking his sample and paying the analysis fee of $2.00, as specified by section four of the fertilizer law. Farmers' samples accompanied by the above fee will be given first order in the laboratory.

Rumor has reached us that there is an impression among the farmers that the analyses of the Fertilizer Control are made largely by students. The rumor is without foundation in fact. The analyses are made by the chemist in charge as far as possible. What work he does not have time to do himself is done by a carefully trained, accurate assistant. Moreover, every analysis is carefully scrutinized by the chemist in charge, and when there is any warrant for it analyses are duplicated by him. The Fertilizer Control laboratory is especially equipped for the work, and is not used at all as a laboratory for the instruction of students.—Geo. Roberts, in charge of Fertilizer Control.

Northern purchasers of fertilizer should report direct to Mr. Roberts at Berkeley.

Los Angeles Markets.

Los Angeles, July 26.

Butter.

Butter has taken a sharp advance during the week, now standing at 57½ for B. of T. with Valley at 55 to 57½.

Northern	12½@13
Eastern	16
Domestic Swiss	16½
Imported do	27½

Eggs.

Eggs have done the sky-rocket act during the last week. Practically every day since last quotations has seen an advance by the Produce Exchange. Some claim this bulling the market has been caused by desire on the part of dealers to force the storage into consumption and that the price to producers did not begin to come to the quotations which follow. However, the wholesalers are holding strictly to these prices in selling and it is estimated now that producers will soon be reaching full up to quotations. The hot weather is probably in part responsible for the big advance. Some dealers are found who prophesy that before the week closes thirty cents will be realized for fancy ranch.

Eggs, fresh ranch	25@27
Eastern and Storage	22@23
Seconds	21

Poultry.

Practically one cent a pound decline is the result of the week in poultry.

DRIED FRUIT.

Regarding the condition of the dried fruit market, the Cultivator representative had an interview with Percy R. Wilding, of the Wilding Brokerage Co., 317 Towne avenue, Los Angeles, and he gave us the following:

Apricots.—A very little trading has been done in this line, a difference of about one-half cent between buyer and seller existing. Buyers offer five and a quarter to five and a half cents in bags for best grades of Southern California apricots. Crop estimates south of Tehachapi place this year's output at 225 to 250 cars, fully one-half of which is off-grade goods.

Peaches.—Market very firm, showing from one cent to one and a quarter cents in advance of early quotations.

Today's market rules for Northern California goods as follows: Choice, 7c; extra choice, 7½c; fancy, 8@8½c, all in twenty-five pound boxes, f. o. b. Northern California shipping points. Crop will be nearly as large as early estimates. Packers all look for still higher prices.

Prunes.—Market very firm on three to three-and-a-half cent bag basis for Santa Clara goods. Outside goods one-quarter cent less. Packers report very hard work contracting with growers who realize the shortage of crop and are holding goods for extreme high prices. While today's prices look high, compared with last year, there is no question but that prices will be maintained and higher market is looked for.

Evaporated Apples.—No quotations out so far on new crop goods. San Francisco packers report few coming in market which are quickly absorbed by local consumption at a round seven and three-quarters for boxes on choice stuff.

Pears, Plums and Nectarines.—No future prices named.

Walnuts.—No material change in local situation. Same applies to almonds.

Honey.—Very little trade in this line, as there seems to be a difference of one-half cent between producer and buyer. Output of honey will not be as large as early estimates.

Raisins.—Present indications are that the raisin market will have a much firmer tone this season as a result of the growers combining as well as the packers for the mutual interest of maintaining the raisin market on a firm basis. Reports from the North show that the growing crop is much lighter than last year and, with light carry over of spot goods, firm prices are granted on both spot and futures.

Figs.—All the leading packers have issued quotations but as it is a little early for this line of fruit very little trading has been done, prices ruling about the same as last year.

Beans, Dried.

Limas	4.50
Pinks, fancy	3.65@3.75
Pinks, rain damaged	2.50@3.00
Lady Washington	2.75@2.85

U. S. CATALOGUE.

The Vermont Farm Machine Co has just issued a hundred page catalogue of its U. S. Cream Separators. It is full of valuable information to dairymen. A request will secure it.

San Francisco Markets.

San Francisco, July 26, 1905.

DAIRY.

Butter is two to three cents higher than last week. On general quotations, though, the market is much unsettled. Some sales of fancy creamery have been reported at twenty-four cents, while others have maintained the top notch at twenty-six cents.

BUTTER—Per lb:

Creamery, fancy	25	@26
Creamery, good to fancy	23	@24
Dairy, choice	20	@22
Store	17	@18

CHEESE—Per lb:

Cal. Creamery, mild new, ex.	11	
Do, choice	9	@10
Young American	12	@13
Eastern, N. Y., Cream	17	@18

EGGS.

The egg market is exceedingly firm, being comparatively easy to secure top quotations. All offerings of selected ranch are quickly picked up.

EGGS—Per doz:

Ranch, selected large	27	@27½
Do, good to fancy	24	@26
Store	18	@22
Eastern, extra	22	@23
Eastern, firsts	19	@20
Eastern, seconds	17	@18

POULTRY.

Arrivals of poultry have been very liberal during the past week, tending to depress the market, and nearly all quotations are lower than last week. Young stock especially easy, two carloads of young eastern stock having been received during the week.

POULTRY—Old Roosters, per doz., $4@4.50; young Roosters, $4.50@6; Frytrs, $3@3.50; Broilers, $2@2.50; Hens, small, $4@5; large, $5.50@6; Live Turkeys, per lb., 18@20c; Spring Turkeys, 23@25c; Ducks, old, $3.50@4; young, $4@4.50; Geese, per pair, $1.50; Goslings, $1.50@1.75; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $1.50@1.75.

FRESH FRUITS.

Apples, per box, fancy, 90c@$1.25; common to choice, 40@75c; Crab Apples, per box, 50c@$1.

Apricots—Per box or crate, 35@60c; bulk, per ton, $20@30.

Figs—Per large box, $1.25@1.75; small box, 75c@$1.

Pears—Per box, Bartlett, No. 1, $1.50@1.75; common, 65c@$1; other varieties, 50@85c.

Peaches—Per box, 35@60c; carriers 50@85c; basket, 50@60c; large boxes, 50@85c; bulk, per ton, Freestones, $27.50@35; Clingstones, $50@60.

Plums and Prunes—Per small box or crate, 35@65c, as to variety; bulk, per ton, $10@12.50.

Nectarines—Per crate or box, 75c@$1.

Grapes—Per box or crate, Seedless, 65c@$1; Fountainbleau, 65c@$1; Muscats, 75c@$1.

Cantaloupes—Per crate, Southern, $1.50@2.25; River, $2.50@3.50; Watermelons, per doz., $1@3; Nutmeg melons, $1@1.50.

Blackberries—Per chest, $1.75@3.

Loganberries—Per chest, $5@6.

Raspberries—Per chest, $3.50@6.

Strawberries—Per chest, Longworths, $3@5; large varieties, $2.50@4.

VEGETABLES.

VEGETABLES—Tomatoes, per box, 50@75c; Green Peppers, per box, Chile 65c@$1; do, Bell, $1.25@1.50; Okra, per box, 90c@$1; Garden Beans, per lb Green, 3@4c; do, Wax, 3@4c; do, Lima 3@4c; Garden Peas, per lb, 3@4c; Cucumbers, per box, 50@85c; Summer Squash, per box, 40@65c; Egg Plant, per box, $1@1.25; Garlic, per lb., 3@4c; Green Corn, per sk, $1@$1.75; per crate, $1.50@2.25.

ONIONS—Per sk, Yellow, $1@1.15.

POTATOES—Per ctl: River Burbanks, in boxes, 85c@$1; in sks, 50@75c; Salinas Burbanks, 80c@$1; Early Rose, 40@55c; Garnet Chile, 40@55c.

DRIED FRUITS.

Dried fruit market has very materially strenghtened all along the line:

Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb. as follows:

Apples—Evaporated, 1905 crop, choice, 7½@8c; Sun Dried, nominal.

Peaches, 1905 crop—Crawford, fancy, 7¼@7½s; choice, 6¼@6¾c; standard, 6@6¼c; Muirs, fancy, 8¼@8½c; choice, 6½@7; standard, 6¼@6½c.

Prunes, 1904 crop.—Sack basis, f. o. b.; for boxed goods add ¼@½c; 40s to 50s, 4¼@4½c; 50s to 60s, 3½c; 60s to 70s, 3c; 70s to 80s, 2½c; 80s to 90s, 2¼c; 90s to 100s, 2c; 100s to 120s, 1¾c; 1905 crop, 3@3½c basis for Santa Clara four sizes, other section ¼c less.

Apricots, 1905 crop—Royal, fancy, 7¼@7½c; choice, 5¾@6½c; standard 5¼@5½c; Moorpark, nominal.

HONEY AND BEESWAX.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

HOPS.

The price of desirable stock is nominal at 24@27½c per lb, according to quality, many producers demanding thirty cents.

LIVE STOCK.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@5½c; rough heavy, 4¼@4½c; common, 3½@4c.

HAY AND FEEDSTUFFS.

HAY—Per ton: Wheat, $9@13.50; Wheat and Oat, $8.50@12.50; Oat, $7.50@11.50; Barley, $7@9; Clover, $7@10; Alfalfa, $6@10; Stock, $5.50@7.50.

New crop Wheat, $9@13.50; Oat, $5.50@11; Wheat and Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice grades, per ton, $30.50@31.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $31@32.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $22.50@23.50.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $25.50@28.50.

FLOUR AND CEREALS.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.45@1.55; White Milling, good to choice, $1.57½@1.65.

OATS—Good to choice, White, nominal; Red, $1.22½@1.30 for new crop.

BARLEY—Choice, No. 1 Feed, 98¾c@$1.01¼; and some fancy up to $1.02½; off grades, 93¾@97½c; Shipping and Brewing nominal; Chevalier, nominal.

CORN—Good to choice, per ctl: California, new large Yellow, $1.45@1.47½; small do, $1.55@1.62½; White $1.37½@1.42½; Eastern Yellow, $1.40@1.45; White, $1.40@1.45; mixed, $1.40.

RYE—Good to choice, per ctl., nominal; new, $1.45@1.50.

CITRUS MARKETS

The market on Valencias continues in very satisfactory condition. The auction markets are showing considerable more strength and higher prices for these. The Western markets are demanding everything in sight of desirable sizes, with a decided preference for the medium to small sizes. Moderate shipments have been going forward, not more than enough for the demand, and prospects are for continued favorable conditions.

The lemon market has remained in good shape, but cooler weather in all parts of the country has cut off the extremely heavy demand, and prices have eased off somewhat from the top prices prevailing a week ago. Sales are still showing high prices and very satisfactory results are being obtained for good stock, both at auction points and in the Western markets.

NEW YORK.

Valencias commanded fair prices at Monday's sale. Seven cars were sold, ranging from 3.75 to 5.10 for fancy goods. Choice 3.25 to 4.15. A few sweets are offered, going at about 2.50 to 3.00. The effect of the hot weather is apparent in much of the fruit arriving, condition being badly off. This more particularly applies to the sweets than to the Valencias.

At Tuesday's sale only three cars were disposed of, almost entirely Valencias, which ranged from 3.10 to 5.05. Some few sweets were sold around the 3.00 mark. Some buying is now being made for storage purposes, such sale being limited to very small quantity. All good fruit commanded a high price and met with a quick sale.

At Wednesday's auction ten cars sold. Market steady on all varieties, though Valencias are practically the only fruit offered. Fancy grades brought from $3.50 to $5.50, even standards selling at $3.40 to $4. A few Sweets that were sold brought in the neighborhood of $3. California lemons continue to bring high prices, fancy selling close to the $5 mark. Choice brought from $3.50 to $4. Grapefruit is the only indication of weakness, selling about $1.85 for fancy and some choice selling as low as 50 and 60 cents.

Wednesday's foreign lemon sale aggregated 13,000 boxes. Stock was in good condition but market indicated a slightly weaker condition, selling about 50 cents lower than formerly, which was due, partly to the weather, which was much cooler.

BOSTON.

Three cars sold on Monday, weather being cool and more favorable for a stronger condition of the market. Valencias ranged from 3.60 to 5.00, lemons ruling around the 5.00 mark.

Only one car sold at Tuesday's auction, which was entirely lemons. They remained close to the $5.00 mark. Weather very warm and pleasant.

Only two cars sold at auction Wednesday. The weather has become very fine and pleasant. Choice Valencias brought $4.50@5; California Lemons, $3.50 to $4.

PHILADELPHIA.

Four cars sold at Monday's auction. Market very firm as to Valencias, fancy bringing 3.95 and choice close to 4.25. Lemons ranged about the 4.50 mark.

Three cars sold on Wednesday. Sale almost entirely of Valencias, nearly all selling for above $4.

* * *

Shipments of citrus fruits since November 1st aggregate 28,042, of which 3449 were lemons.

The dairies about the city of Berkeley are compelled to submit every cow in their dairies to the tuberculin test before they are permitted to have a license for selling milk in that city. The ordinance has existed for some time but has not been enforced, but the present board of health proposes to fully enforce the ordinance.

Trophy Winners at 1903 Los Angeles Show

In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.

My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

Is Deep Orchard Cultivation Beneficial?

One Case Where it Has Paid Exceedingly Well to Stir Up the Soil and Incidentally Do a Job of Severe Root Pruning.

"Well, really, I can not explain to you whether subsoiling which is so deeply done that large numbers of the good sized roots are cut off causes the roots to send out a number of other and smaller roots into new soil and thus secure new feeding ground or what the scientists' explanation may be of results following this deep plowing. I am simply a practical man who used deep, subsoiling methods in which I tore out vast quantities of roots and received as a result far healthier, stronger-looking trees, setting a larger quantity of fruit than ever before in the history of the orchard. Therefore, I believe in root pruning by subsoiling. For the scientific explanation, you must go to others."

This, in a few words, is the position taken by Mr. B. B. Wuest, of Alhambra, to the writer in his orchard a few days ago. We had heard of his efforts to improve the soil condition by subsoiling and wishing some further information along this line of a former article under the above heading, we boarded the electric car and were landed at his front door, when we proceeded to walk down through the orchard in question. It is but a few miles from the center of Los Angeles, and along its front extends the Monrovia electric line. Hence the values under the present real estate movements all about the city are such that Mr. Wuest has decided that there is greater value in his orange grove as residence property than there is to be used in producing oranges. Consequently, cement sidewalks and oiled streets, gas pipes, water pipes and electric poles and other features familiar to the present real estate movement were on all sides and in this case it was not without sadness that we noticed it.

The orchard trees, we found, were loaded with fruit, trees very dark green and thrifty looking. There are twenty-four acres in the place from which this year there were marketed six thousand boxes of fruit at fair prices. Notwithstanding this, property valuations, all the way from $7 to $30 per front foot, make the real estate movement seem more attractive to owners of such property.

But, to return more directly to the object of our errand, we sought out Mr. Wuest, who, with shovel on shoulder, was directing the work of furrowing and irrigating. Hence, we were able to observe the practical side of the work better than usual. From him we secured the history of the trees and the advantage which he deemed the deep cultivation to be giving to him. First, he bought the place when the trees were three years old, maintaining it under the original form of cultivation, running six furrows between rows at each irrigation, some times the water barely reaching the lower end of the row before having to be shut off and turned to the next row. After twelve years of such treatment, the trees had become of little value as producers of first class fruit and the owner determined that something must be done to restore them, or else uproot them. Getting some information regarding deep culture and believing it would be beneficial to the trees to tear off many of the surface feeding roots and loosen up the plow sole which had formed, he purchased one of the strongest and best made subsoiler plows and, putting four strong mules on, put it in fifteen or sixteen inches in depth, driving the horses as close as he could to the trees without injury to the limbs, and went from end to end of the orchard, snapping off large roots. This first subsoiling was done in the fall and was followed by a long rain, which was very fortunate. On being asked if the first effect of this subsoiling was not to set back the trees until they recovered from the shock of so many large roots being cut, Mr. Wuest remarked that entirely contrary to that, from the very first, the apparent effect on the trees was such as to indicate an immediate improvement. The following spring the trees set one of the largest crops in their history and today a better looking orchard is hard to find, though the owner apologized for its condition at the present time, as he remarked about the corner lot feature having attracted more of his attention recently than orchard culture.

Natural Growth of Navel Orange Tree.

One of the first questions that we asked was "how would you handle a young orchard if you were to start in with trees from the nursery and carry it up to the same age as this one?" and he at once replied that he would first use the subsoiler, before planting, and continue its use before every irrigation. By that means he would keep the roots where he considered they would do the most good and keep the soil open to the admission of the air so that the air would reach the lower levels, thus being valuable to the plant food there contained and in a period of a very few years he would, he believed, have a very magnificent property.

As to the time of year of using the subsoiller, he answered, "At all times," but almost immediately qualified by saying "Of course, in spring time when setting fruit or growing the very young fruit, or after a rain, when the ground is very moist, common sense would dictate keeping out with such deep culture." But in the fall, when the ground is dry and the fruit is large enough not to be affected by the shock, and preceding each irrigation, he would use the subsoiler. Instead of running six furrows between trees, he now runs two furrows and he considered those two furrows do vastly more good than the six formerly did. The work of preparing for the water is much greater than before, but the work of cultivation is much less than formerly so that he considered the question of economy does not enter into the discussion in considering the two methods of work.

In detail, his method now is to put on four good stout mules or horses, put the subsoiler fifteen or eighteen inches deep, going two ways through the orchard on either side of each row. This makes a square around every tree in the orchard. The ordinary turning plow is then taken with two horses at-

(Continued on Page 115)

an interesting story hangs. Its first chapter concerns the 'insectorium.'

The unpretentious building with the pretentious name recently made its appearance on the public gardens side of the Agricultural department. The Insectorium has been erected in the interests of science, and for the development of the fruit-growing industry. This purpose is not fulfilled, as might at first be thought, by providing a home for indigent fruit flies, after a vigorous orchard career. On the contrary, the insects have been gathered in to grow fat and flourish, so that an alien insect may act the part of destroyer. When, through the instrumentality of the State Entomologist, the last consignment of fruit-fly parasites was introduced from Brazil, the Australian season synchronising with their heyday in South America was unfavorable to them. There were few fruit-flies carrying on business in the State, and, consequently, the parasite imported under contract, finding no scope for its peculiar abilities, languished and died of hunger or home-sickness, or both. So that this should not occur again, the Insectorium was erected and at present some 10,000 odd flies are thriving under State management and control.

The second half of the story is supplied by Mr. Compere.

"I broke my outward journey at Suez," he remarked, "and proceeded to Palestine—not on a pilgrimage, but to secure some red scale parasites for the California government. I shipped a collection and set sail for Spain. Two years previously I had located the insect which parasitizes the codling moth in Spain, and I collected 4000 specimens for the California government. That was the first time codling moth parasites had been introduced into California and I was pleased afterwards to hear that the consignment arrived in splendid condition without the number being depleted by deaths. When I arrived in California I had a talk with Mr. Ehrhorn, the State Entomologist, and he told me that the parasites which had been kept in confinement had reproduced themselves in 44 days.

"After discharging these two engagements, I set about securing the parasite of the fruit fly. For this purpose I proceeded to Brazil, landing there on March 19th. It was a good time of the year—early spring—for my purpose, and I had no trouble in collecting a sufficient number of the insects. I secured 1000 members of the Staphlynidae and a number of Ichneumon wasps, both of which are terrors for fruit flys. The former are beetles in their fully developed state, and bred on the way out. Their daily food allowance has been a pint of blowfly maggots, and the way they attacked them afforded an indication of the manner in which they will demolish the fruit fly. The other insects are in the chrysalis stage of their existence, and as they traveled at sea in the refrigerator chamber of the boat, they have not yet hatched out.

"The consignment arrived in splendid condition, and the beetles have been liberated in the Insectorium. From observation, I feel certain that in a little while, with so much of their natural food available, an interesting struggle will commence. Personally, I have not the least doubt that they will be successful."

The fearful destruction which the fruit fly has visited upon the fruit interests of Australia is such that we wish for that country the most complete success from Mr. Compere's work with the parasite.

PRUNE OUT THE BERRIES.

This is the time of year to prune out the blackberries, dewberries and raspberries and other vines of that class. Cut out all canes which bore fruit this year, clean up all the ground, burn the old brush which may be infested with scale, spray the young shoots which will bear next year's crop with whale oil soap, or even strong soapsuds, to kill off the young scale which may be on them. Then manure heavily and do not forget that the blackberry, especially, is a gross feeder.

Do not tolerate the long canes but cut back to three or four feet and force the branching.

Don't wait till next spring to cut out the old canes. Their usefulness is gone forever and the strength they now require may just as well go into new canes, thus making more bearing wood next year.

CHIMNEY SOOT OF VALUE.

Chimney soot, says the American Fertilizer, is one of the richest fertilizers known. That from coal is very rich in ammonia. When coal is burned ammonia is set free, and during the various changes which take place during the process sulphite and carbonate of ammonia are both formed.

Soot is a highly compound substance, containing in its composition not only ammonia, but lime, sulphuric acid, nitric acid, acetic acid, chlorine and iron, nearly all of which are valuable, directly or indirectly. The value of soot is well known in England, where it sells for about 10 pound a ton, or about $48. It is often thrown away as worthless by those who do not know its value, but careful farmers should save every ounce for use. Sprinkled around some kind of plants, it often prevents attacks of insects and the rains then carry it down into the earth, where it does duty as a fertilizer. Soot from coal has been once thought to be a very worthless substance, but experience and science have taught us to know better.

NATIONAL RECIPROCITY CONVENTION.

The Committee on Arrangements for the National Reciprocity Conference, to be held in Chicago August 16th and 17th, hereby announces that, while the call for delegates has been mailed to all national, State and local agricultural and live stock associations, whose addresses could be obtained, it is not the intent to deny a seat in the convention to any farmer or stockman who desires to manifest his interest in the matter by taking advantage of the reduced railway rates to be in force, and attend the sessions of the convention.

It is to be hoped that every effort will be made to secure the presence of representative men from every part of the corn belt and contiguous territory. This section in particular has a deep interest in the future of the European markets for our farm products.

The committee not only desires that all interested communities send a delegate or delegates, but that every individual farmer or stockman in America who hopes to see this movement to broaden the outlet for our grains and meats succeed shall enroll his name upon the lists now being made up in the committee's office.

The movement for this convention is occasioned by the tariff of Germany which discriminates against American farmers.

FRUIT OUTPUT REDUCED.

The output of apricots will be much lower than anticipated, and a correspondingly higher price will prevail than was feared at one time. Regarding the condition as observed from the Santa Clara valley, we note the following from the San Jose Mercury:

"Large sales have been made in Europe and America at very low prices. These sales have been based upon the "outside" supply from Vacaville and Winters and the southern counties. These localities have nearly cleaned up, and as usual the prices have advanced for Santa Clara 'cots. The outside apricots have sold from 5c to 6¼c to the trade with about 7c for what is called Fancy Royal. These prices are unnecessarily and absurdly low. They were made by those who do not own or grow a pound of 'cots and under the impression that the crop would be enormous. It now develops that the crop of 'cots will be less than that three years ago. This is due in part to sunburn and an increased shrinkage of ½ pound at least.

Prices today in the market are: Prime, 6c; Standard 7c; Choice, 8c; Fancy, 11c to 12c.

Regarding prunes: "It seems now to be the universal opinion that the fruit crop of all kinds will be below the earlier estimates. As a consequence all buyers and packers have increased the price to the trade, and also to the producer.

The commercial packers are not offering freely, as they do not feel sure of buying of the grower at anything less than a 3-cent net base. We hear of some offers to the grower at that price and feel sure the trade price will be raised from ¼ to ½ a cent.

The secretary of the agricultural society has made up a list for approval of the State Board of Examiners, the balance of all claims incurred by the Fair Association. The payment of these claims will free the society of all debts for the first time in many years. Some of the warrants are drawn in payment of debts contracted ten years ago.

A dispatch from Washington states that the Forest Service is planning to collect tree seeds on a large scale, to be used in the work of reforestation in the work of western reserves. Nursery work, or planting, is now in progress, or soon will be taken up in the Santa Barbara, San Gabriel, Modock and Warner mountain reserves in California, besides reserves in Colorado, Nebraska, New Mexico nad Utah.

VARIETY OF PEAS FOR GREEN MANURING.

The Cultivator received some time ago request from a number of orange growers at Redlands stating that sample of "Canadian Marrowfat peas" had been mailed to us and that they were recommended to them as being the equal or superior to the Canadian white field pea and that they had failed to find the latter and asked opinion as to the desirability of the peas sent.

The peas sent to us were submitted to a number who were qualified to judge and almost invariably they decided that instead of being a "marrowfat," which they were not in any respect, they were a mixture of the Canadian white field and the Prussian blue, the greater proportion of them being the pure Prussian blue pea. Regarding the desirability of the pea for green manuring, readers may note in the letter below from Mr. James Mills, of Riverside, that it is the variety which he will most largely plant this season. Those who have been asked regarding the two varieties and the comparative values of them, usually say that they have a slight preference for the Canadian white, partly because it gathers the nodules fully as well, has heavy top and root growth, and the seed being smaller, at the same price is slightly more economical. However, we have learned from market quotations on peas that the very best that can be secured on the Canadian white, f. o. b., Los Angeles, jobbers price to the wholesalers, is three to three and a quarter cents, while the Prussian blue have been sold, f. o. b. Los Angeles, in car lots, at $2.40 per hundred, or, in ton lots, at $2.50.

Regarding the desirability of these two varieties of peas, we wrote to Mr. James Mills, also to Mr. J. B. Neff, and asked their opinions. Their letters follow. Mr. Mills says:

"I cannot advise you as to the Canadian marrowfat peas. I did use them some ten years ago. I did not succeed, however, with them, but my want of success may not have been the fault of the peas. I am using only the common Canadian field pea and the Prussian blue pea. There is no question about the superiority of the field pea over all others. If these can be had it would be wise to get them. I am using this year twenty-seven different kinds of cover crops. I will be better able another year to advise you in this matter. I would say, however, that the Canadian field pea and Prussian blue pea have no superiors in my judgment. We had splendid success with them last year. This year we purchased 60 tons of the Prussian blue peas because we could buy them cheaper than the others and because we are entirely satisfied with the results obtained from this seed heretofore.—James Mills, Supt. A. H. F. Co.

On the same points, and especially regarding the difference between the Marrowfat and the field pea, note the following from Mr. Neff:

"I do not think there would be much difference in the fertilizing value of the Marrowfat peas and the Canadian field peas, provided the peas were equally thick on the ground. But the Small White, or Canadian field pea, will require a less quantity of seed per acre to get a good stand, as the seed is smaller, 60 lbs. per acre being sufficient.

There is but one kind of Canadian field pea, as far as I know, and that is a small white pea, always round as shot, and not wrinkled like the Marrowfat or other table varieties. The Canadian field pea is known in the northern part of the State as "Small White", or "Niles Peas," possibly because they are grown largely near Niles.

The home grown seed has not given me quite the satisfaction the eastern grown seed has, as it is not usually so plump and does not germinate so well."—J. B. Neff.

Many planters will this year take the precaution of inoculating all the seed with the nitro-culture bacteria, which will cost about $1 per acre, additional to the seed. Of course, where the soil has been used for the same variety of cover crop before, and inoculated at that time, it is probable there may be sufficient in the soil so inoculation each year is unnecessary. In fact, it is said to increase from year to year and one method of inoculating soils is to take samples of the soil from an old field which has cultivated peas and simply scatter over the ground of the new field.

Regarding the amount of seed required per acre, the usual planting is about sixty pounds for the solid acre. By solid acre, we mean the actual surface planted, figuring out of course, the space between rows when planted in orchards. Some planters, however, maintain that the Prussian blue may with advantage be planted slightly heavier than the little white, but this is on account, principally, of the fact that the seed are larger, consequently fewer number per hundred pounds. But as to growth, both root and top, there seems to be no choice between the two.

As to vetches and lupins, there seems to be less interest this year than formerly, but this is probably on account of inability to get the seeds in quantity, as can be done in the case of peas.

$1500 FROM TWO-BITS.

Mr. Musser told us a few days ago of a case of increase which we believe has few equals. A gardener near Long Beach produced this year $1500 worth of tomatoes from twenty-five cents worth of seed. Of course, the tomatoes were early and netted to the grower large prices, but no more than many another grower could have netted in the market at the same time, but it certainly looks good to the outsider to see a gardener getting such increase as that.

NATIONAL BEEKEEPERS.

The next National Beekeepers' convention will be held at San Antonio, Texas, October 28th to November 1st.

A STATE INSECTORIUM.

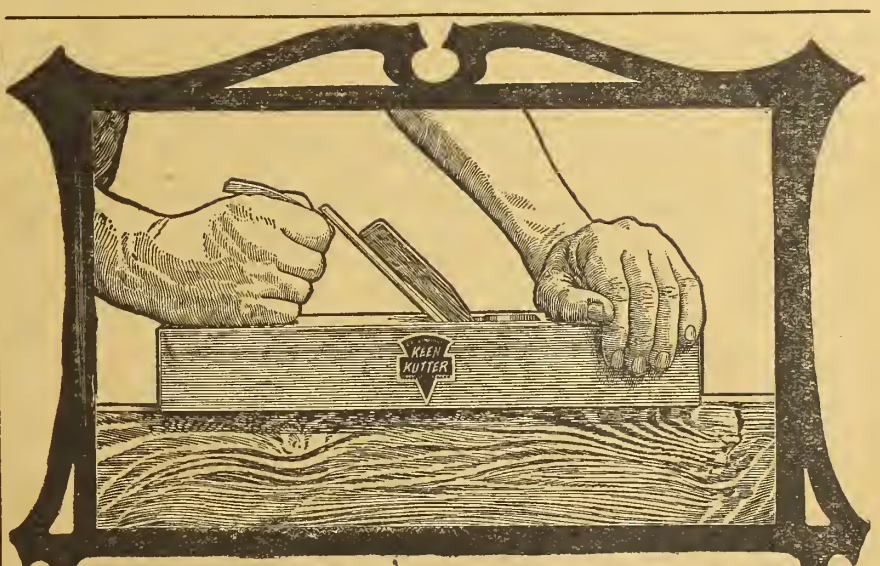
When in San Francisco some time ago, it was our pleasure to visit the office of the State Horticultural Commission, at which time we noted the crowded condition of the offices. In fact, the principal reason for the existence of the rooms would appear to be at first glance that of an insectorium, for on the walls are cases of specimens and all about all three of the rooms are cages used for the breeding of beneficial insects and other cages for the breeding of injurious insects for "feed" for such of the beneficial parasites as may be on hand for breeding purposes. This crowded condition is to be regretted and with it all is the more important fact that the rooms are not fitted for the work in hand. Both Mr. Ehrhorn and Mr. Carnes referred to the fact that as good work as should be done was not possible under the conditions which faced them and they regretted the fact that the State did not purchase a plot of ground with a small building on it for their uses.

In this respect, we are behind that far-away country of Southwestern Australia, for we note, from the Western Mail, published at Perth, in its issue of June 3d, a description and illustration of the insectorium used there by Mr. George Compere, who, as is known by our readers, is employed by the California Horticutlural Commission and the Australian Department of Agriculture to work for the interests of the two countries. The article in question refers to the insectorium and to Mr. Compere's work for the two countries as follows:

"Bronzed and travel-weary, with the dust of three continents and the spray of as many seas comparatively fresh upon him, Mr. George Compere, the State Entomologist and grand chief insect hunter, returned to Western Australia on Thursday, May 25th. Mr. Compere has arrived after one of his famous jaunts "round the world for a bug," and his most treasured possessions are a collection of ticketed and neatly assorted insects, a fund of scientific information, and a glowing account of the success of the system of 'parasitising' orchard pests.

Mr. Compere's latest trip, like several of his earlier ones, was made for the purpose of securing a supply of those insects whose natural food is the fruit fly, and which the tenets of the new school of entomology advance as a certain remedy for the depredations of that particular pest in orchards. A considerable amount of money has been expended in securing this parasitical insect, but an optimistic department considers that it is money well spent, and that the advantage of the expenditure will be repaid one hundred fold when the beneficial parasites are introduced. Mr. Compere has now succeeded in introducing the parasites, and the work of fighting the fruit fly will be commenced in earnest.

On the subject of the pending battle



In Actual Use

Keen Kutter Quality tells in the actual use of the tool. Keen Kutter Tools are not retired by an occasional knot or tough piece of material. They are made to stand hard work and lots of it. They are as good as new after poor tools have gone to the scrap heap. The

KEEN KUTTER

brand covers a complete line of tools. In buying any kind of tool just see that the name Keen Kutter is on it and you have assurance of full satisfaction. Keen Kutter Tools have been Standard of America for 36 years and are the best that brains, money and skill can produce.

Some of the kinds of Keen Kutter Tools are: Axes, Hammers, Hatchets, Chisels, Screw Drivers, Auger Bits, Files, Planes, Draw Knives, Saws, Scythes, Tinners' Snips, Scissors, Shears, Razors, etc., and Knives of all kinds. If your dealer does not keep Keen Kutter Tools, write us and learn where to get them. Every Keen Kutter Tool is sold under this Mark and Motto:

"The Recollection of Quality Remains Long After the Price is Forgotten."

California Horticulturally

By John Isaac, Sacramento, Cal.

NEW METHOD OF PACKING FRUIT FOR SHIPMENT.

A packing house has been constructed and outfiitted at Antioch which, if successful, will revolutionize the fruit industry of California. Some account of this has been given in the upper country press, but as yet the work is being carried on quietly and without any flourish of trumpets. The establishment is the outgrowth of several years of experiments which have proven so successful that several of our leading fruit growers have put money into the enterprise to remove it from the laboratory stage and establish it as a commercial enterprise. The process, as we understand it, consists of packing fruit in air tight cases, from which all air has been extracted by means of suitable machinery, and this air is replaced with nitrogen gas. It is claimed for the process that the gas arrests decay, destroying the bacteria of the ferment which causes decomposition, and that any article packed in this manner will retain its condition indefinitely. There being no disease germs in the package it is impossible for decomposition to set in and as a result the fruit so packed will retain its qualities until it is desired for use. By this means fruit can be shipped in a fully ripe condition to any part of the world with the assurance that it will arrive at its destination in exactly the same condition it was in when shipped. It can be kept in stock by the purchaser until he desires to use it, and he can be certain that when he opens the package it will be in good condition. There will be no glutting of the market, for if the demand will not consume the imports of one day they can be set aside until they are required. It will do away with the necessity for refrigeration, and in short, if successful, will completely revolutionize the fruit industry, and add millions to the wealth of California. That the projectors have faith in their enterprise is evidenced in the fact that they have erected very extensive works at Antioch, that they have done it quietly and without any desire of notoriety, and that they have put very large sums of money into their buildings and the necessary machinery. We shall watch the outcome of the practical tests of this new enterprise with a good deal of interest.

* * *

THE ORCHARD OF THE FUTURE.

J. R. Barnes, writing in the American Cultivator, says:

"I can't help finding myself casting about for a plan of apple orcharding that will give us a form of tree more easy to spray, easier to thin and gather the fruit from, and perhaps commence to produce fruit at an early age. I believe this form of tree and condition of orchard is bound to come, that the old form of tree and plan of apple orcharding is bound to go. The scale and lack of the right spraying apparatus will force this, even if other reasons do not."

This is a discovery which the California orchardist made long ago, and which was forced on us by our climatic conditions. We long since discovered that low pruning and thinning, and so shaping the tree that it was within easy reach in every part, the keeping of the head so low that the trunk should be well shaded from our hot sun and the ground around it so protected as to resist the great evaporation of the hot dry season, was the only practicable method of handling orchard trees. The heading of our trees low at the same time make them easier to spray and brings the fruit within easy reach for picking. The Eastern friut grower has evidently something yet to learn from California, and is beginning to solve problems which we have encountered and overcome ling since.

* * *

GRASSHOPPERS DISAPPEARING.

The grasshoppers which have been more than usually troublesome in the Sacramento valley this season, have acquired their wings and have generally thinned out or disappeared. There has been a great deal of unnecessary dread experienced from this pest this season and from many newspaper reports it might have been thought that California agriculture was doomed. It is really too bad that these exaggerated reports are allowed to be sown broadcast, for, being copied in the eastern press, it gives those who are not better informed the idea that the whole State of California has been devastated by this terrible locust. The fact is, that the California locust is an innocent visitor compared with his Rocky Mountain cousin; but this is not known by the eastern readers, nor by many California readers, and the reports which have been published about it for some weeks past would make it appear to be even more to be dreaded. The truth is that we have locust visitations every year in some parts of the State, especially along the foothill sections of the Sacramento and San Joaquin valleys, and these visitations we shall have so long as the pests can find suitable breeding grounds left for them in those sections. Some seasons are more favorable for their propagation than others and, in consequence, in those years swarms are larger and more destructive than in others. This year the swarms have been especially large in the Sacramento valley counties, but have not been nearly so large or so destructive as in some seasons in the past; at the same time they have done an immense amount of damage to orchards, vineyards and gardens bordering on their breeding grounds. The total of this damage to the State has been very light, although unfortunate individuals in the path of the swarms have suffered heavily. There is but one means to stop it and that is by breaking up their breeding grounds, and as these are the rocky, gravelly lands of the foothills, which have no value except for grazing purposes, it will not likely be done; any other relief is temporary and limited. Poisoned baits will catch many, but ten will escape where one is caught; burning over the breeding places while the hoppers are yet on them will destroy many, but some will escape, and the operation is at once costly and dangerous. The pasture for the year at least will be destroyed, and there is grave danger of the fire escaping and doing more damage than the grasshoppers would.

To sum up in a few words: We may look for this pest every year, some years worse than others; there is no method of annihilating them; we can use such remedies as are available for reducing their numbers; the State of California is safe as a whole, although some small localities may suffer; it is an injustice to our State and our people to spread such exaggerated reports of this pest as has been done by the sensational press the present season.

* * *

LITTLE DAMAGE TO FRUIT FROM HOT WEATHER.

An unusually long heated spell visited the State beginning of July, covering the first ten days, during which time the mercury in Sacramento county reached the hundred mark daily, and on one occasion touched 110, a temperature never before recorded in this section, doing a great deal of damage to fruit on the trees and grapes on the vines. Even this heat was exceeded in the central and upper portions of Sacramento and San Joaquin valleys. The early reports of the damage which had been done from this excessive heat were, as usual, very greatly exaggerated, and in some instances it was stated that the total crop in some sections was destroyed. sufficient time has now elapsed to judge of the extent of the damage and, while it has been severe in some cases, as a whole, very little damage has resulted. In the more exposed situations fruit which received the full force of the sun has been cooked on the trees, but these cases are rare, in other instances some of the fruit has been damaged, but in the worst cases not over 25 per cent of damage has been done, and on the whole, but few specimens have been injured on the tree. So it may be stated that in spite of early reports there has been no damage to fruit from the hot spell.

FRENCH WALNUT CROP.

Owing to an unusually cold spring and to long continued rains all vegetation has been retarded and fruits have developed and ripened slowly. The season may be said to be two weeks behind the average one. The walnut trees have shared in this, and, besides, the excessive rains were, in one locality, in the month of June, subjected to a very heavy storm accompanied by hail.

The young nuts in consequence were slow to form, but since the 20th of June—a period of about two weeks—the weather has become suddenly warm, developing into a "heated spell," with occasional showers, and the general conditions for the growth of the nuts have changed for the better.

The nut trees are looking fresh and clean in their rich, green foliage, and the nuts themselves. now of the size of small marbles, are promising a normal yield.

Some of the dealers in the nut districts have been disposed. until these better weather conditions set in, to minimize the prospects, predicting a harvest much below the average; but others more recently are raising their expectations, and predicting fuller and more satisfactory results in every way. Combining these reports with our own personal observations, we believe that there is good ground for thinking that the nuttage for 1905 will be a fair one, well up to the average—this as to quantity, and, we see no reason why it should not be so as to quality.

ALFALFA is now attracting much attention everywhere. Do not forget that Alfalfa needs heavy doses of POTASH to insure successful growth.

We have a book which is full of valuable information to all farmers who are experimenting with Alfalfa, and will gladly mail it free of all cost to any one who will be good enough to write for it.

Address, GERMAN KALI WORKS
93 Nassau Street, New York
Meyer Wilson & Co., San Francisco, Cal., are sole agents for the Pacific Coast.

Naturally, it is taken for granted, because of the variableness of the weather and the impossibility of forecasting the adverse contingencies that may arise in the three months before maturity, one cannot speak definitely as to the exact quality of a current season's nuts until the time of actual harvesting. At present writing, we may summarize by saying that should the weather conditions continue normal throughout the summer the prospects are favorable for a normal crop.—C. P. Mason, U. S. consul at Grenoble, France.

Young trees should not be trimmed too liberally, as too much foliage taken from the tree weakens its feeding power.

A successful plum grower is necessarily a good botanist.

CITRUS FRUITS

By C. A. Day. Pasadena

SOME THINGS DETERMINING PROFITS.

In the matter of citrus fruit culture, the orchardist strives to secure quality, quantity, merchantable size, and to control the time of maturing of the fruit. In these four essentials we have the whole problem of successful citrus culture in a nutshell.

The term quality in this connection has reference to appearance, flavor and ability of the fruit to carry well. The quality of soil, the inherited qualities of the tree, climatic conditions, pernicious insects, artificial fertilization, and the general method of culture enter into the problem of the successful growing of citrus fruits.

There may be certain adverse conditions of soil and qualities of tree that it may be impossible to entirely remedy, although susceptible of great improvement.

The fertilization and general culture are tntirely under the control of the orchardist and may be used in the improvement of quality, quantity and control of size and time of maturing. In the matter of quality there is a broad field for scientific experimental work. In the matter of quantity, size and time of maturing there is a better understanding as to what methods will produce desirable results, although there are some points that remain to be cleared up. The lemon grower seeking to secure the principal crop of lemons for the summer market, proceeds to prune and adopt a method of culture at the required time to force the tree into bloom and by after culture to bring his lemons to the proper size when the market will give the best returns. The orange grower failing to adopt well planned and timely methods of culture and fertilization does not produce desired results. It is my firm belief that we have the power to largely control the quantity and size. The control of quantity will depend upon the ability of the orange tree to set and hold the new crop of fruit and the size will depend upon the culture which follows. The orange, like other fruit bearing trees, is inclined to bear in alternate years, a full crop of fruit, and in the off years a lighter crop running to large off sizes. In the years when the tree bears a full crop the aim of the orchardist is by fertilization and proper culture to bring the oranges up to the regular sizes of merchantable fruit. This is done not only to secure regular sizes but to increase the output of fruit. It is a well known fact that off sizes of oranges, consisting of the very large and the very small sizes, are discounted by the trade and bring a lower price than those of regular size, the difference ranging from ten to twenty cents less per box.

There is a belief among some of our orange growers that the annual dropping or thinning out of the new crop some time after the fruit has set is due to weather conditions, such as hot days, and that this dropping can not be controlled by fertilization or soil culture. Climatic conditions may have a tendency to cause dropping, but it is in connection with other conditions which are under the control of the orchardist.

In off years a thin setting of fruit will give a good per cent of large sizes and in these years the large quantity of these sizes make them a drug in the market and they are consequently discounted. If we can control and increase the set of fruit in the off years we will reduce the quantity of large sizes and increase not only the quantity of regular sizes but the general average of the crop. Another thing to be gained by increasing the crop of the off year is that the price of fruit generally rules higher, in these years than in those of a full crop. I think we may safely say that a severe dropping of oranges is due to a lack of vitality in the tree, from a lack of the required supply of available plant food or the draft made upon the tree by a large stock of scale.

The scale is always supported at the expense of the tree. It draws on the supply of nourishment which should go to make new wood and fruit. The tree should be kept clean and free from scale and the fertilizer should be applied at the right time to stimulate the tree. There is no doubt as to the method that should be adopted in the fertilization of the orange orchard in full bearing. Fertilize moderately every year. Fertilizer applied spasmodically or not at all will result in large crops in some years, followed by very light ones.

The crop of oranges is always borne on the new wood, and it is necessary to grow a good quantity of new wood every year for the succeeding crops of oranges. To secure good crops of oranges every year the tree must be given plant food in sufficient quantity to not only mature the present crop but to grow the new wood for succeeding crops.

A bearing orange tree grows its supply of new wood in the summer and fall when the temperature of the soil has been raised sufficiently to cause nitrification to take place. There is no growth of new wood on a bearing orange tree in the spring and early summer. The fruit spurs, blossom and newly set fruit of the spring time are largely the product of the reserve material stored up by the tree in the previous summer and fall. Trees and plants store up during the principal growing season a reserve of elaborated food material in the form of sugar and starch. This provision of nature is for the purpose of propagation and continuance of the species. A part of this material in the form of sugar, starch and oil is stored in the seed, which is used at the time of germination of the seed to grow the root system, and the germ, or sprout, to the surface, where it expands its leaves in the sunlight and the new plant is rendered capable of taking the carbon from the atmosphere and the mineral elements and nitrogen from the soil and begin the manufacture of elaborated plant food on its own account.

The tree not only stores up this reserve material in the seed, but under the bark, for the growth and development of the blossom and newly set fruit of the succeeding year. The fertilizer must be applied at a time that will render it available for the use of the tree during the growing period. Some orchardists supply an available commercial fertilizer in the fore part of the summer to stimulate a growth of new wood on the orange tree. Some apply a limited amount of available nitrogen at the beginning of the blossoming season near the surface. The application of nitrogen in excess of what the tree can use is a waste, as denitrification destroys the nitrates not used. The most critical period of the year for the orange tree is from July 1st to November. The growth of the fruit and new wood and storage of reserve material for the blossoming time must be all carried forward at the same time and requires an abundant supply of available plant food, thorough irrigation and cultivation. With the tree carrying a heavy crop of fruit conditions must be most favorable in order to secure a medium crop the following year. Under such conditions a crop of black scale will frequently turn the balance against the grower.

SCUTELLISTA.

Editor Cultivator: Last year the scutellista cleaned up the black scale on our orange orchard pretty well, but during the cool weather this spring the scale became pretty bad and a great many have hatched. Now nearly all the old scale have grubs or flys. Will the scutellista work on the young scale so that we will not need to spray? Will send you under separate cover branch of tree showing size of scale. Also will enclose a couple of insects found on orange trees; are they harmful or beneficial? If harmful will spraying destroy them?—C. F. E. R., Orange.

Regarding the work of the scutellista on the scale now hatching, such as was sent by Mr. R., will say that we think they will succeed in parasitizing the majority of these insects. The scale are now about the size of a pinhead, though many are more nearly grown. The old scale on the stem which you sent are almost every one of them inhabited by thrifty young scutellista. Of course, they will have no immediate effect upon the young scale, but will doubtless be ready to deposit their eggs underneath the living scale a few weeks later. The insects on the leaves in the bottle which was sent are, so far as we can determine, nothing but the aphis lion, a beneficial insect which preys upon the plant aphis which may have infested the trees. There may have been other insects in the bottle but, owing to there having been some liquid in the bottle which gummed up and destroyed the life of nearly everything that may have been on the leaves, its was almost impossible to be sure which one was meant.

Hundreds of trees set every year die because of the neglect of the owners. It is not always the fault of the nurserymen.

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

WILL WE GET BAILEY?

Rumor has it that President Wheeler of the State University recently went East for the express purpose of securing Prof. L. H. Bailey, of Cornell, to succeed Prof. Hilgard as Dean of our Agricultural College. "'Tis a consumation devoutly to be wished."

What lends color to this rumor is the fact that since we first heard the above report Prof. Bailey has come to this coast and is presumably to come south from the Portland exposition to look over the ground and consult with "the powers that be" at Berkeley.

While it would be saying too much to state that California's horticulture hangs in the balance, it would become us to hold our horticultural breath in expectancy. Such an alliance means much to this State and Coast. California and Bailey! What a union of strength! The comparative standing of our State in relation to our farm and orchard products is too well known to our readers to need repetition at this time, and to our most prominent horticulturists the name (and fame) of Bailey is nearly as familiar; but to those who are as yet unacquainted with his life and works, we insert the following sketch:

Liberty Hyde Bailey was born at South Haven, Michigan, March 15, 1858. Graduated at the State Agricultural College in 1882. Next two years as assistant to Prof. Asa Gray, at Harvard College. Next four years as professor of horticulture at his alma mater, University of Michigan, whence he was called to the chair of horticulture at Cornell in 1888. In June, 1903, he succeeded the veteran I. P. Roberts as Dean of the Agricultural College and Director of the Experiment Station at the latter place, which means a life position for him, unless called elsewhere. Besides being a prominent member of all great societies and organizations for the advancement of science and of agriculture, and horticulture in particular, he is the author of more works of standard authority than anyone in the same line, living or dead. Though still a young man the volume of his work, considering its general acceptance and high standing, has been enormous, for there is no branch of horticulture in which Prof. Bailey has not one or more works generally accepted as of the highest value.

With Prof. Bailey at the helm, with his great knowledge and experience, ably seconded by our own Prof. Wickson, what possibilities the near future holds in store for California we hardly dare guess. Certain it is that the name of Bailey will alone give our agricultural industries a greater stimulus than any other force we could add, while his keen foresight and tireless energy would soon place us in a position such as to meet the wishes of the most expectant.

Bailey and Wickson would make a remarkable working team, for in the East, among the horticulturists of note, Prof. Wickson has been called the "Bailey of the Pacific Coast," a title of which any man might justly be proud. We take the liberty of here printing Prof. Bailey's estimate of Prof. Wickson: Some years ago, in answer to a letter from the writer, an assistant writing at Prof. B.'s request, advised to "cultivate Wickson; he is the grandest, broadest man you have on the Coast."

HOUSE PLANTS.

The cultivation of house plants has a refining and quieting influence on families where they are grown; they adorn the house as nothing else can, and give to the cheapest furniture an air of elegance which no other ornament can impart. And the influence of flowers is not confined to the house or household where they are cultivated; they are a most graceful form of charity to the poor passer-by who has no means of gratifying his taste for the beautiful. To him, blooming flowers, surrounded by their leaves of different shapes and shades, even when only seen at a distance, through a parlor window, give a positive pleasure which those more accustomed to such gratifications can scarcely appreciate. It is impossible to overestimate the effect of youthful association and daily companionship with such exquisite shape and coloring, which foster in the minds of children a taste for simple and natural forms of amusement and recreation.

Henry Ward Beecher declared that he always found house plants an infallible test in selecting acquaintances, neatness, cleanliness, and innumerable virtues being the usual accompaniments of a love of flowers. Then, what delightful subjects of gossip they furnish; and how many reputations have been spared when house plants were at hand, and their various merits, their growth, and means of culture to be discussed! How they grow into the affections, too, as we watch their green sheaths pierce the rich brown mould, and leaves and blossoms expanding into loveliness!

OILS FROM PLANTS.

Croton oil is extracted from the seeds of Croton tiglium, an evergreen tree, growing 15 to 20 feet in height, a native of the East Indies. It is prepared by reducing the seeds to a powder, which is placed in bags, and pressed between iron plates. The oil is allowed to stand fifteen days, and is then filtered. The residuum is saturated with twice its weight of alcohol, heated to 140 degrees, and the mixture pressed again. The alcohol is afterward removed by distillation. The oil is a very active purgative, very acrid, and dangerous, unless carefully administered. Even those employed in preparing and pressing the seeds are affected with irritation of the eyes and violent purging.

Cinnamon oil is obtained from the bark of the cinnamon tree, Cinnamomum Zeylanicum, much cultivated in Ceylon, Cochin China and other places in the East and West Indies. The fragments which remain after peeling, sorting, and packing the marketable bark, are roughly powdered and macerated in salt water for several days, and then distilled. The oil is at first of a yellow color, but soon assumes a reddish-brown hue. It has an odor intermediate between that of cannamon and vanilla, but possesses in a high degree both the sweet, burning taste, and the aromatic smell of cinnamon. Eighty pounds of fresh, newly prepared bark yield about 2½ ounces of oil, which floats upon the water, and 5½ ounces of heavy oil, which is precipitated to the bottom of the receiver.

The best camphor oil is furnished by Dryobalanops Camphora, a lofty-growing tree of the island of Sumatra. The wood is tough and durable, and is used for shipbuilding, its strong oil-scent saving it from the attacks of shipworms. The oil is obtained by incision and flows as a pale yellow liquid, called the liquid of camphor of Borneo and Sumatra. It consists of resin and a volatile oil, having a camphorated odor, and has been used in scenting soap and other perfumes. Solid camphor is also found in the wood, especially in old trees. It differs from ordinary camphor by its greater hardness and brittleness. It is much prized by the Chinese, who ascribe many virtues to it. The camphor oil we get in the U. S. is from the camphor tree so common in California, native to China, Japan, Formosa and adjacent islands.

Clove oil, or oil of cloves, is obtained from the flower buds of Caryophyllus aromaticus (Myrtaceae). It is associated with resinous, gummy and astringent matter. The buds yield 17 to 22 per cent of oil, which is aromatic and acrid, and has been used as a condiment and stimulant carminative. It is also employed by distillers and manufacturers of soap. An oil called clove oil is distilled from the leaves of the cinnamon, which is said to be equal in aromatic pungency to that made from the clove.

VEGETABLES ON THE FARM.

A good vegetable garden is conceded by most farmers to be most convenient and profitable, and yet comparatively few farmers have one. The reason usually given for the neglect is that they do not have time to attend to one. The truth of the matter is that the garden requires a little care daily, and demands thought, patience and system in order to secure success and profit. Unhappily, these are just what most farmers dislike, preferring to tend the larger crops, where less thought and more muscular power is required. They would be glad of the rich product of the garden upon their tables, and the pleasure, health and profit they would yield to the family, but the habit of neglect in this particular has become so deeply implanted that no common influence will break it up.

A shipload of lily bulbs from the far east—the Orient—will be among the produce to pass through Portland, Oregon, in the near future, on consignment to a New York house which imports great quantities of the flowers every summer. It is estimated that there will be 15,000 cases of the bulbs and if they are all brought across the Pacific at once 150 cars would be required to transport them across the United States. At first reading this seems like a great undertaking for one firm, but it must be understood that this nation is to a great extent composed of flower-admirers, and such a quantity of bulbs would not go very far after all towards supplying the demand.—Pacific Homestead.

The peer of all cut flowers is the gladiolus. What a profusion of different markings there are among them! What glorious spikes of beauty! We made three plantings so as to have a continuity of bloom. We couldn't get along without about a bushel of the bulbs. Also the dahlias are necessary to the complement of beauty.

Public benefactors spring up, now and then and the good they do is immeasurable. The latest benefactress is Mrs. Anna Bidwell, of Chico, who has given that town 1402 acres of beautiful land to be used as a public park.

There are thousands of rich Californians who can do something for their towns in the way of public improvements, such as donating money for street beautifying, for parks and for gardens, which will not only add value to their own property, but bring pleasure into the lives of others.

There never was a kingdom grander than California, and by the lavish hand of art it may be made the glory of the world.

SANTA FE IS THE WAY

General Agricultural Notes

WINTER CABBAGE.

Cabbage sold so exceedingly low last winter that it is possible there may be slight interest in it this year but have some inquiries as to the best time and methods of handling this vegetable, we give below a few points regarding it from the pen of that interesting writer who has had large experience in California vegetable gardening and who has heretofore given readers of the Cultivator several interesting articles. We refer to "Q. A. L.," of San Gabriel.

* * *

"The time for planting seed for fall and winter cabbage depends somewhat upon the variety and whether you wish to market in the fall or midwinter. Referring to my notes I find I sowed seed of Burpee's Surehead cabbage last year on April 26th, and transplanted into the field June 21st and 22nd. The cabbage was marketed September 13th. Any time from April 15th to August 1st will do to sow the seed. It will be evident, however, that the later sowings will not mature until midwinter.

Almost every gardener has his own method of handling the plants. I sow the seed thinly in rows not longer than 150 feet and the rows about twenty inches apart. Unless on a large scale I prefer hand sowing. The ground should be mellow and moderately fertile. If one can find the time to transplant the young plants when they are about three inches high into rows as I have described for the seedlings it will give a stocky, fibrous-rooted plant that will transplant into the open field with less check than plants that have not been transplanted. Whether transplanted or not, the seedlings must be watered and cultivated well and frequently. If they have been sown too thick, thin out so that they will stand not closer than two inches in the rows.

Transplant into open field as soon as the plants are four or five inches high. Be very sure to cut the leaves back at least a half as soon as lifted from the seedbed. This will reduce the surface through which the juices of the plant are evaporated before the roots take hold in its new quarters. One of the prime secrets in growing tender and sweet cabbage is that from start to finish it should never be allowed to receive a severe check in the growth. This is much more difficult to accomplish in our arid climate than where the rainfall is abundant. The cabbage is a gross feeder and it is worse than useless to attempt to grow a large crop of fine quality on land that is not made fertile. I have used one hundred tons of stable manure per acre, annually for early cabbage, and that, too, upon land that had been brought up to the highest standard of fertility by previous years of good care.

"It is fair to state, however, that such heavy manuring was not necessary for the later crops. When the earth became worked up by the advancing seasons the plants seemed able to get their necessary quota of nitrogen from less than half the quantity of manure that was essential earlier in the season; when, because of the low temperature, the nitrogen was not avaliable.

"Whether or not there is money in growing plants for the trade, depends on so many things that I cannot answer in a single word. Such work pays east of the Rockies, and if begun in a limited way here, I think it could be made to pay. Berry boxes are too bulky to use for temporary potting. The modern paper pot would seem the ideal package, but I grew cabbage, tomato and celery plants in large quantities for several years in flats, containing 50 to 100 plants. Necessarily, the work if done on a large scale, would have to be "on orders." That is, contract work. They are so perishable. They grow so quickly to a limit where they become valueless unless planted into permanent quarters—that unless one is growing on "orders" the risk is so great as to invite failure.—Q. A. L., Barbour Ranch.

* * *

In addition to what Q. A. L. says, we may add that Wickson's California Fruits says:

It is wise in most parts of California to start plants in a seed bed in September or October, irrigating the ground well to guard against drying out on land not naturally moist. In the warmer coast regions good plants can be grown at this time of the year in the open ground in drills eight or ten inches apart for hand-hoeing. In the interior, where temperature extremes are liable to be greater, a cold frame, or covered seed bed, may be used to protect the young plants against hot, dry winds. In small garden practice the use of the seed-box is often handier. Plants should be given space enough to grow thriftily and should be transplanted to the field when conditions are right for planting out in the locality.

Plants started in September may be planted in the field as soon as they are strong enough, when an early winter crop is expected. Where this is not favored by the local climate, it is still advisable to have early grown plants, and in garden practice they can be several times transplanted and thus kept small and stocky for planting out when soil and weather are right for it. Where the early winter is apt to have quite severe frosts, plants started in the fall in the open air can be transplanted to cold frames until this danger is past.

FACTS ABOUT ALFALFA.

Alfalfa seed weighs sixty pounds to the bushel. For a hay crop sow twenty to thirty pounds of seed per acre. For a crop of seed, sow fourteen to eighteen pounds per acre. Sow clean seed.

Screen alfalfa seed before sowing to separate the dodder and other weed seed. Dodder is the worst enemy of alfalfa.

Do not cover the seed too deep.

Alfalfa does not attain maturity until the third or fourth year; therefore do not sow it expecting to get the best results in less time.

Alfalfa grows best on a deep, sandy loam, underlaid by a loose and permeable subsoil. It will not grow if there is an excess of water in the soil. The land must be well drained.

Alfalfa is a deep feeder. Plow land deeply.

Cut for hay when the first flowers appear. If cut in full bloom the hay will be woody and less nutritious.

Cut for seed when the middle clusters of seed are dark brown.

To make alfalfa hay cut in the forenoon and let it wilt; then rake in winrows and cocks, and stack or put in barns with as little handling as possible, before the valuable leaves become too dry or brittle.

It is not safe to pasture either cattle or sheep on alfalfa, as they are liable to bloat, when it is fed green. Feed them the hay or practice soiling.

There is no better or cheaper way of growing hogs than to pasture them on alfalfa. One acre will furnish pasturage for from ten to twenty hogs per season.

Horses can be pastured on alfalfa.

Alfalfa hay is not a complete ration. The best results are got by feeding it with corn fodder, ensilages, wheat or oat straw or roots. Alfalfa contains large amounts of protein.

Six to ten bushels of seed is the usual yield per acre.

Keep the weeds mowed and raked off the first season or they will choke out the crop.—Ex.

GOOD GOPHER CATCHERS.

We note the following in the San Bernardino Times-Index:

C. H. Miller, the Verdemont rancher to whom a party of boys recently turned over the pet coyotes of the fire department, "Hans" and "Fritz," finds them valuable as gopher catchers on his ranch.

The rancher declares the coyotes have the best dog or cat ever built beat a mile as gopher hunters. They will quietly sneak about the field looking for signs betraying the presence of gophers. When these are found, the coyote will lie down, instinct telling it which way the gopher will emerge from the ground. After a while the coyote has dinner.

Errata.—By error the article "A State Insectorium", not completed on page 101, was continued on page 100 instead of 102.

The Chinese Boycott.—California is destined to feel the blow China is striking at our commercial industries. Already one of the largest houses in San Francisco has been ordered by its foreign agent to "cancel all orders, as business is practically suspended."

The beginning of this trouble dates back to the enactment of the Chinese exclusion law, which the government has been strictly enforcing for the past few years. The provisions of this law are severe, and enforcing them has created much ill feeling on the part of the Celestial government. To get even a "boycott" has been declared against American goods and from this on we shall reap the harvest we have sown. That Germany is quietly aiding in intensifying the feeling against America, appears very probable, because she is pushing more industriously for occupation in that quarter of the world than even Great Britain, but it goes without saying that every nation in the old world is looking on with ill concealed glee at the fine fury China is working herself into against America and her commerce. A Chinese immigration law was necessary, but it never should have been permitted to develop into a law better entitled "An act of persecution" than an act of exclusion. It is here the boycott fever has its origin.

Untold Wealth for Our State.—The announcement was made this week that a most gigantic scheme has been perfected to bring water in unlimited quantity from the Owens river to supply the entire country around Los Angeles, for a distance of a hundred miles or more. Not only is the future of the city of Los Angeles assured, no matter how great may the city grow, but the country round about is to be supplied with purest water from the Sierra mountains, and the desert, in Southern California, made to become as valuable as the richest tracts of land now under the most ample irrigation system. This water is to be brought 240 miles through mountains in great conduits, to Southern California, possibly to the limit of land on the south, which is San Diego county. It is estimated that 30,000 inches of water will come into Southern California, supplying the San Fernando and San Gabriel valleys and the towns now being built and those that will be built with all the water needed for every purpose whatsoever.

Los Angeles will have a supply of water greater than that of any other city of equal size in the world, and the San Fernando and San Gabriel valleys will be converted into the most productive region in the world.

We can scarcely realize the future of this part of California when all doubt about water supply is forever settled, as it will be, when the mighty Owens river empties its snow melted waters at our very doors. The source of this wondrous supply is located between Sierra Nevada and the White Mountains in Inyo county. It is 100 miles in length and between five and six miles wide. "The water commission for the city of Los Angeles," says the Times, "has bought the southern forty miles of this valley, which gives it the riparian water rights to the flow of Ash creek, Cottonwood creek, Turtle creek, Lone Pine creek, George's creek, Shepherd's creek, Independence creek, Oak creek, Black Rock springs, Division creek, Goodale creek, Clear creek, Taboose creek, Tinemaha creek and Fish springs."

In the valley there are already about fifteen canals which take water from the mountain streams for irrigation purposes. But this water, soaking through the porous gravel beds, finds its way back to the river and becomes part of the supply bought by the water board.

Some of the mountain streams in that valley are among the most magnificent in the West.

Cottonwood creek is a magnificent mountain torrent plunging down the eastern slope of Mount Whitney to lose itself in the gravel beds of Owens river.

For the seven miles of its length the stream is a series of waterfalls of great scenic beauty. In the summer season it carries a flow of water greater than that of the entire San Fernando valley. In a distance of seven miles the stream has a fall of over 6000 feet.

It is from this stream that the engineers expect to develop sufficient power to bore the twenty miles of tunnels that will pierce the mountains barring the gravity path of the conduit which will bring the Owens river into the San Fernando valley."

The origin of Cottonwood creek is a vast body of snow from twenty to twenty-five feet deep in the spring and early summer, and seldom gets as low as ten feet, even in the hottest season. From this eternal supply will come the life-giving water for people and land in the country of California's glory. About four years will elapse before the water will reach the San Diego line, but in that time one hundred thousand people will have come into the valleys, which this mighty conduit will make a living oasis. Orange and lemon groves will abound in future where today only cactus and sage brush grow. Magnificent herds of cattle and sheep will cover the plains and we shall become, in deed and in truth, a country blessed of God and thrice blessed of man. Great industries will spring up along our coast and prosperity, such as Southern California has never witnessed, will everywhere abound.

* * *

The Cow in California.—With the introduction of all the water farmers can possibly use will come a new industry into Southern California. Heretofore fruit growing has been really the principal industry. In the north the diversity of interests has been greater. From the boundary line to San Francisco, general farming has been the occupation of a majority of the people, especially adapted to grain raising and alfalfa growing, Northern California has been making wonderful strides in the last few years, adding dairy to agriculture until that section has placed itself on an independent basis. The tide of agriculturalists from the East has been toward the undeveloped lands of the great northern counties of California, where lands were cheap, water abundant and cattle raising a sure and lucrative occupation. Coming down into the central part of the State, like progress has been made in population, but not so much progress along the lines of developing the possibilities of the cow. Fruit, vegetable and grain growing have occupied the most energetic of the people, although dairying to a considerable degree has constantly developed.

But it will remain for Southern California to exhibit the most stupendous strides in dairy production when the country is thoroughly under the influence of the new dispensation which is promised when the Owens river is brought into it, as it will be, by means of one of the greatest systems of irrigation the world has ever known. Then the thousands of acres which now remain uncultivated will be growing alfalfa, with other grains, and hundreds of dairies will be scattered about where now there are none. That dairy interests are destined to become most important, if not the most important, of any in the State, may reasonably be anticipated, when we remember that last year they amounted to $20,375,567, while fruit only reached a total value of $25,000,000.

The Sacramento Union makes the observation that "the fact that dairy products are imported into California in constantly augmenting quantities ought to be an encouragement to local development of a most remunerative business. Both cheese and butter reach California from the East and also from abroad, and the quality is no wit superior to the California product. California herself exports condensed milk and cream and the figures for the current year show a gratifying increase of $100,000 over the previous year. The State ought not only to produce her own butter and cheese, but she ought to turn her imports of these goods into exports, and she will certainly do so when her ranchers rise to their opportunities."

They will rise to their opportunities in Southern California when they can raise grain and alfalfa at reasonable cost, and produce butter, equal to the best now imported, for less than the cost of handling the product in the market today. Mighty things are in store for the cow in California in the nevt few years.

* * *

To Degrade Secretary Wilson.—The extent to which the enemies of rate legislation will go to accomplish their designs—namely the defeat of rate legislation in congress, is seen in the effort now being made to degrade the Secretary of Agriculture in the public mind, by repeatedly attacking his office, with the purpose of driving him from the cabinet. Mr. Wilson, who all the years he has been Secretary of Agriculture, has been the steadfast friend of the farmers and producers of the country, and the sturdy opponent of the trusts and combines which have been robbing the people, is now beset by these forces of public plunder, as the country believes, who charge that he is permitting dishonesty to develop in his department; that his disbursement of funds has been illegal, and that a state of affairs exists in his office as compromising to his administration as existed in the postoffice department. So far as Mr. Wilson is concerned, nobody believes he would permit dishonesty in anything he has to do. He may have dishonest employes under him and they may do things which are illegal and which he knows nothing about. In a great department, such as the one over which he presides, no man can exercise absolute, personal supervision, and it is an easy matter for a clerk, or for several of them, to do things, under cover, which their chief is ignorant of, unless something occurs to bring them to his attention. It would seem that Mr. Wilson's whole trouble has been that in his big way he has been so honest that he could not bring himself to believe that anybody associated with him in his work in the department could by any possibility be dishonest. He never believed it was possible that thieves could be at work in his pet institution. It has not been shown that any great amount of irregularity has been committed, but enough has been discovered for the enemies of Mr. Wilson to attempt to embarrass the President and force the Secretary of Agriculture to retire from the cabinet. Underneath these repeated attacks may be seen the cloven foot of the enemies of rate legislation. It is believed to be one of their schemes to divert the attention of congress and the country from the discussion of this paramount subject, and by degrading the Secretary of Agriculture frighten public officials into silence when the measure shall come before congress for discussion.

Most profound regret exists in Washington over the repeated attacks made upon the Secretary of Agriculture, because, apart from politics, he is recognized as by far the best Secretary of Agriculture this country has ever had, and that he has done more for agricultural and horticultural interests than any other person in his position has accomplished.

* * *

"John D. Rockefeller is the greatest criminal of the age." These were the words of Gov. Robert M. LaFollette of Wisconsin in an address delivered before the Illinois State Chautauqua Assembly Sunday last. The address was a flaming arraignment of corrupt State and National legislation and of the monopolies.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Buyers are reported in Santa Clara county offering three cents for prunes.

The olive crop in the Menifee valley is reported particularly heavy this year.

The Crawford peach crop in the northern half of the State is reported short and unsatisfactory.

Articles of incorporation of the Spencer Seedless Apple Co. were filed in San Francisco last week.

Prunes and peaches around Campbell are ripening very rapidly and the prospect is for early drying this year.

The Zante packing house at Porterville is finished. New machinery will be placed in time for the coming citrus crop.

The crop of summer apples in the district south of Soledad in Monterey county was largely destroyed by the recent hot weather.

The prune crop around Rockford, Tulare county, is said to be very good and will be ready for gathering unusually early this season.

Contracts were let last Saturday for the erection of an addition eighty by eighty feet to the present house of the Lindsey Fruit Association.

Prof. Albert West, of the Department of Agriculture, at Washington, is in Southern California to aid in the investigation of the walnut blight.

The grape crop in the southern portion of Fresno county and northern part of Tulare, is reported considerably damaged by the recent hot weather.

Picking Thompson seedless grapes is now in progress in Tulare county. One cent a pound is being paid in small lots; at the drying sheds $17 per ton is paid.

The Ernst Luehning company at Suisun has dried and shipped a very large quantity of apricots this season, some of which were sent direct to Germany.

A correspondent from San Jose writes that prunes are still dropping badly, and will not average over one-third of a crop. However, the fruit is ripening very rapidly.

Apple growers of the Hood river district, in Washington, last year received from $2.10 to $2.50 per box, f. o. b., for Newtown Pippins. This season they expect to receive as high as $3.50.

Word comes from Florin, Sacramento county, that the Tokay crop has been damaged fully twenty-five per cent in the region from the Mokelumne river south to the county line in the north.

The Hallengren Winery, 80x64 feet with 10,000 gallon storage tanks and fermenting tanks for handling 150 tons of grape at a time, will be completed in time for this year's crop, when about 600 tons will be handled.—Sonoma Farmer.

Manager Sprague, of the California Fruit Exchange reports four cars of pears and peaches sold in eastern cities one day last week, which brought banner prices. One car sold for $1552, another for $1195, another $1450, and the fourth for $1314.

Nearly all of our local exchanges report special prices received for lemons in the East, but the best price yet reported is that from Blanchard's packing house, at Santa Paula, last week, when a half car of standards sold for $1763 net, which is equivalent to about $9 per box.

It is announced that the Colton Fruit Exchange will pay to growers about September 1st, a dividend of $18,000. This sum is the difference between packing charges and actual cost.

Our correspondent writing from Healdsburg says that canneries are mostly working full time now. Peaches, blackberries and plums are being put up. Cling peaches are netting the growers $50 a ton, free stones $25, blackberries $30. At that price the berries are hardly worth picking. Green prunes selling at from $20 to $30 per ton, short crop.

The apricot harvest in the district known as the Avenue, north of Ventura, is about completed, the crop being very heavy. According to the figures of the growers, it amounted to about twelve hundred tons, making about two hundred and forty tons, or twenty-four cars of dried fruit. At five cents a pound, it is figured the orchardists will receive a total of $24,000. Nearly five hundred people were required for about three weeks' time to handle the crop.

AGRICULTURE.

The hop crop in Sonoma county is estimated at two-thirds of a crop.

The Pomona Grange will hold a meeting at San Jose, August 12th.

The sugar beet factory at Los Alamitos commenced its fall campaign this week.

It is expected that the Chino sugar factory will commence the fall campaign about August 14th.

Harvesting around Glenn is nearly over. Barley has turned out well, wheat very light, and prospects for corn very good.

The Rockyford canteloupes from Exeter are now being sold in the markets along the coast, and are declared of superior quality.

Threshing began in the Hoopa valley, Humboldt county, last week. The yield of oats and barley is better than for several years.

Hundreds of hop pickers are reported camping at Wheatland ready for hop picking, which will commence about August 12th.

Work on the new beet sugar factory, one mile southeast of Visalia, was begun last week. Part of the machinery for the building is already on hand.

A forest fire the first of the week in the south end of the San Bernardino mountains swept over several thousand acres and destroyed a lot of hay.

The hop crop in the North Yakima, Washington, district is reported to be about the same as last year, there being a good deal of loss from the hop pests.

M. H. Durst, of Alameda, gives out an interview advising hop growers not to sell during the next thirty days. He says that prices are now easy at eighteen to twenty cents with the chances largely in favor of better prices being paid in October.

LIVE STOCK.

There is talk of building a new creamery at Gilroy.

Material for the new creamery at Glenn has been ordered.

The Kings Co. creamery at Hanford has just ordered a $600 cream ripener.

L. M. Cornell, of Porterville, is shipping horses to the Los Angeles market for sale.

Farmers around Jacinto, Glenn county, are trying to organize to build and operate a creamery.

Fred Hughler, of Indiana, is looking over the country about Lindley with a view to starting a cattle ranch.

The Wool Growers' Association will hold its fall wool sale one day between October 13th and 20th at Marysville.

The amount of butter in cold storage at Los Angeles is about 200,000 pounds less than at this time last year.

The McKim Brothers shipped from Imperial last week, a car of hogs for which they received six cents at Los Angeles.

G. A. (Buttermilk) Smith has sold his entire creamery business both at Los Angeles and in Central California to a syndicate.

A valuable milk cow died within an hour after being turned into a patch of green Egyptian corn near Antelope, Sacramento valley, last week.

A drove of thirty hogs broke into a vineyard near Roseville last week and proceeded to make a meal on a bran mash poisoned for grasshoppers. As a result eight pigs died.

J. L. Harrison, of Pasadena, will leave shortly for New York and Boston, to be gone for a couple of months. He will pick up a few fine chickens with which he will grade up his pens.

The Patterson Ranch Co. have selected four hundred head of steers from their Topo ranch in the Simi and taken them to Oxnard, where they will be put into early feeding at the sugar factory yards.

MISCELLANEOUS.

The deer season in Santa Cruz county opened August 1st.

Several miles of county roads are being oiled in Tulare county.

The government has decided to install a new guage in the Sacramento river at Red Bluff.

Canneries at Marysville are short of help, notwithstanding higher prices are paid over previous seasons.

Government experts are examining both forks of the Yuba river with a view of seeding them to forest trees.

Figuring from the number of school children in the State, California has a population of 1,722,661 in this year of 1905.

The time for burning the bonds in the Escondido irrigation district has been definitely settled to take place on September 9th.

A number of boys at Summerland one day last week organized a rat bee and succeeded in killing three hundred and sixty-four of these pests on that occasion.

The Southern Pacific company has recorded patents from the government on two tracts of land in Riverside and San Diego counties. One patent covered 132,302 acres and the other 114,257 acres.

Work on the construction of the new Yosemite short line railroad from Jamestown to the National Park, is to begin this week. The company has signed contracts for fifty miles of steel railing, delivery to begin in September.

The city of Los Angeles has secured options on the Owens river water, amounting to about 25,000 inches. An election is to be called to vote bonds totaling about $20,000,000 to bring the water to the city, a distance of 240 miles.

The supervisors of Orange county have signified their intention of creating a levee and protection district to control the flood waters of the Santa Ana river from West Orange to the ocean, a distance of about ten miles, at a total cost of $78,000.

Practically every redwood lumber mill in the northern part of the State is said to be overrun with orders. The question of supplying lumber fast enough is a problem that now confronts most of the Coast mills. Never before has there been such a tremendous demand for lumber.

It is stated that a new company has been formed to manufacture men's hosiery, such as used by miners and lumbermen, also other knit goods at the Woolen Mills buildings in East Napa. The company also plans the operation of an ice factory and cold storage establishment at the same point.

J. F. McIntyre, of Ventura, well known as a leader in the honey industry, says that the yield is about 7000 cases of honey, which will run about six tons to the 100 cases, or something like 437 tons of sweetness. This yield comes principally from Los Angeles, Ventura and Santa Barbara counties.

The Sierra Railway Company announce that they will build a road from Oakdale, Stanislaus county, to Angels Camp, Calaveras county, with branches at Modesto, Knight Ferry, La Grange and Centerville, the total length of the main line and branches to be 124 miles. The company is capitalized at $5,000,000, of which $124,000 has been subscribed.

"STAYING POWER."

The Country Gentleman printed some time ago a statement regarding the great staying power of pigeons. The item, which was later quoted by the Petaluma Journal, is:

The tremendous staying powers of the pigeon is illustrated by the following from the Country Gentleman: A Utica (N. Y.) letter says that an exhausted pigeon, which had on its legs a tag inscribed "A. C. H. 396," has been found at Dolgeville, Herkimer county. Adolf C. Horn, a pigeon fancier, lived in Dolgeville until a year ago, when he went to the new Dolgeville in southern California, taking his pigeons with him. It is supposed that the bird is one of his flock which returned to its old home. Such a flight, however, is unparalleled."

A letter from Mr. Horn says: "I did not bring any birds to California. The bird which went back to Dolgeville, N. Y., I believe I sold to an eastern fancier." Thus a remarkable "flight" of a bird is reduced to one of imagination.

C. H. SESSIONS, ASSOCIATE EDITOR

THE COVERED MILK PAIL.

That a covered pail will keep a good deal of the dirt out of the milk cannot be denied, and that purer and better milk can be obtained by its use than by the usual open pail must be conceded. Just to what extent a covered pail will keep out objectionable bacteria, so far as we know, has never been determined, but that it will keep out a large number of them has been established as a fact. The Connecticut experiment station has carried on some experiments along this line that may be of interest to some of our readers.

The covered pail used by that station consisted of an ordinary milk pail with a tight fitting cover. Near one side of the cover there is a round hole about four inches in diameter into which is soldered a funnel with a fine wire gauze at the bottom. When the pail is to be used a few thicknesses of strainer cloth are fitted into the funnel and made to rest on the gauze at the bottom. The cloth extends over the edge of the funnel and is held in place by a small funnel or a broad ring which holds the cloth in place by pressing it against the sides of the stationary funnel.

From this description it will be seen that the pail is a very simple one, and is easily cleaned. To test the efficiency of the covered pail, two cows were used for the experiment that gave about the same amount of milk each. Cow No. 1 was milked into the covered pail one day and the second day cow No. 2 was milked into the same pail, while on the alternate days the open pail was used for the same cows.

The milk was then stirred and the amount of dirt in each pail determined with the result that the covered pail contained 37 per cent less dirt than the open pail. After the milk in the open pail had been strained it still contained 53.4 per cent of the dirt originally present. Therefore, the covered pail kept out 63 per cent of the dirt, while the ordinary strainer, after the dirt had soaked in the milk during the time of milking, removed only 46.7 per cent. It was further found that in the milk from the covered pail 29 per cent of the total number of bacteria were excluded as compared with that in the open pail and 41 per cent of the acid-forming species were also prevented from gaining access to the milk. Straining the milk from the open pail removed 11 per cent of the total number of bacteria and 17 per cent of the acid-forming species.

Contrary to what one would expect, the milk from the covered pail did not keep sweet so long as did the unstrained milk drawn into the pail, nor did the strained milk from the open pail keep sweet so long as the same milk unstrained. The difference in the length of time it kept sweet, at a temperature of 70 degrees F. amounted to seven hours. The explanation of this is stated to be that straining probably removes certain species of bacteria which, if present in large quantities, prevent the acid-forming species from growing rapidly.

While it is not likely that many farmers will adopt the covered milk pail, it would seem as though those who are selling milk to customers in town could do so to great advantage. As has been shown, a large number of bacteria are excluded by the use of the covered pail, and if milkmen would explain this to their customers and show them the precautions they are taking to deliver clean milk, they would be able to work up a lot of select customers who would be willing to pay a premium for such milk. Try it. It pays to be ahead of the majority.—Farmers' Tribune.

GOATS' MILK.

Interest in the milk goat is spreading. One of the latest to show an awakening along that line is the northern end of the Pacific Coast. The Ranch in a recent issue says:

We would like to hear from parties who raise milk goats—and can probably help make an occasional sale for those who have any to sell. The following brief notes should be of interes to those who keep milk-giving goats. Those who are familiar with the subject pretty nearly all agree in their claims as to the value of goats' milk for invalids, for children and for cookery. Some of them regard it as most beneficial when taken medicinally for certain diseases or ailments.

Goats' milk is especially recommended for infants because of its similarity in composition to mothers' milk—and medical literature is full of instances of success attending the use of this milk with children that, previous to its use were rapidly wasting away.

Most authors who are assured of the complete digestibility of goat's milk, and who recommend its use above all others, base their opinions on results obtained from feeding children several months old.

The trouble in this country has been that the goat was so long an object of ridicule among those who never undertood its value, that a false impression has sprung up, or rather exists, in regard to keeping goats or using their milk. The American public is largely of the opinion that goat milk has a peculiarly disagreeable odor or flavor. This it not true in properly managed dairies. Those who fully understand the causes that produce ill flavored milk in cows, would not expect any radical difference in the goat. If the goats are permitted to roam the streets and alleys at will, and pick up garbage, one may expect to find the milk off in flavor; again the principal source of bad odor so frequently noticed in goat's milk is the dirt which falls from the animal's body into the milk at milking time, another common cause is the buck, whose skin emits the odor so characteristic of nearly all breeds of goats. It is specially objectionable to have the buck near at milking time, as the milk readily absorbs the odor.

Sharples TUBULAR CREAM SEPARATORS

We want you to know Tubular Cream Separators as they are

Investigate the low can and enclosed gears. Tubulars have neither oil cups, tubes, nor holes—they oil themselves. They have bowls without complicated inside parts—hold the world's record for clean skimming, durability, capacity, easy turning and easy washing—save half the work—greatly increase the amount and quality of butter—are wholly unlike all other separators. Write for catalog R-200

MEALFALFA

Reg. U. S. Patent Office

FOR HOGS

Alfalfa being a highly protein food it is just the thing for hogs, as it not only prevents the loss of fat in the animal, but builds it up. When mixed with other grain into a slop, you have a rich green bulky food, a first-class ration for your hogs, that will fatten them quickly and put them in fine condition for market.

The brood sows will thrive on it and it will stimulate their milk flow. For young pigs you have a food hard to beat. MEALFALFA is in the finest form for mixing with skim milk and then you have a slop that has nourishment in it and will fatten the little pigs rapidly, make them hardy and stimulate growth by furnishing them the material for blood, muscle and bone.

MEALFALFA is put up in 100-pound sacks. A very handy size for shipping.

DE LAVAL DAIRY SUPPLY CO.
9 and 11 Drumm St., San Francisco 107 First St., Portland 112 2nd Ave. South, Seattle

The milk of properly fed and properly managed goats has no flavor to distinguish it from cow's milk, except perhaps its extra sweetness and creaminess; in short, it is only distinguishable by its superiority.

Milk goats are found in all parts of the world, but, with the exception of Switzerland and a few of the other European countries the varieties are so numerous that no effort has been made to classify them.

It is stated on good authority that there are in Switzerland no less than sixteen pure breeds of goats. The Swiss breeds now represented in the United States are the Toggenburg, the Saanen, and the Schwarzwald, and importations are increasing very rapidly.

Although the origin of our native American goat is obscure some very excellent milkers are often found among them.

So far there has been very little dealing in milk goats in the United States, and therefore no really definite price. The common American goats can be purchased at from $2.50 to $10.00, the basis of price depending entirely upon the ability as a milk producer.

The best milkers of Malta sell at from $18 to $25, while the various breeds of Switzerland bring about $20 each. In England prices are very much higher. A very fine milker in the latter country will sometimes bring as much as $40; if a pure-bred Toggenburger the price is apt to be $100 or more.

The first question most people ask concerning the goat industry is: "How much milk will a goat give?" This question can not be given a definite answer. Such matter as the healthfulness of the animal, character of feed, regularity of feeding, breed, age, etc., have an all important bearing on the quantity of milk produced.

A doe that yields less than a quart a day is not considered a good milker; if she yields two quarts a day she may be regarded as profitable. Indeed, it is stated by German writers that many goats yield ten times their body weight of milk annually, and exceptional animals as much as 18 times their weight.

The price to be obtained for the milk will depend largely upon circumstances. In a few instances where some of the milk has been sold the prices have ranged from fifteen to twenty-five cents per quart. In these cases the milk was not used for hygienic purposes, and no attempt was made to produce and care for it according to recognized sanitary methods. Not less than 25 cents per quart should be obtained where the milk is properly produced for consumption by puny children and sick people.

GROOMING THE HORSE.

Regarding the importance of keeping the horse in healthy condition by his "bath"—daily grooming—the Farmers' Tribune says:

The skin of a horse, like that of other animals, is a mass of excretory pores, which, if kept open, give a constant flow of watery fluid discharges, carrying off the effete waste material, which has performed its proper function in the maintenance of the body. The epidermis also is composed of an infinite number of glands which constantly pour an oily secretion to the surface, which is essential to keeping the skin flexible, as well as furnishing the necessary nourishment for the hair to keep it soft and glossy. It will not do, therefore, for these pores to get clogged, for in that case the skin soon would become dry, rough, hard and diseased; nor is there much danger of it except when the horse is hard at work. Then the secretion of watery fluid is heavier than when the animal is idle, and if the sweat is allowed to dry on the skin dust will accumulate, mixing with it and, if not cleaned off, fill and clog the pores. As a result the skin will not only become diseased, but the whole system more or less deranged. The impurities, unable to escape through the skin, will accumulate in different places and give rise to blisters, which, if neglected, may lead to blood poisoning, or something else nearly as bad. By regular, thorough grooming, however, all this will be prevented, the pores kept open and a healthier, thriftier condition of the animal maintained. A horse having a thick, tough skin will endure a tolerably sharp currycomb, which, used on another with a thin, tender skin, would be a positive cruelty. Whatever accumulations of dirt may be on the hair after the use of the currycomb a thorough cleaning out of the skin should follow by the aid of a good brush.

SHEEP DIPS.

The British Board of Agriculture allows of the use of no dip for sheep which is not accepted by the board. Amongst those accepted by that board are the following:

* * *

Lime and Sulphur.—Mix 25 pounds of flowers of sulphur with 12.5 pounds of good quick lime. Triturate the mixture with water to a smooth cream, and transfer this to a boiler of 20 gallons capacity. Make up the volume with water to 20 gallons, boil and stir during half an hour, when the liquid should have a dark-red color. If yellowish, continue the boiling until the dark-red color is obtained, keeping the volume at 20 gallons. When the liquid has cooled, decant off from any small quantity of insoluble residue, and make up the volume to 100 gallons with water.

* * *

Carbolic Acid and Soft Soap.—Dissolve 5 pounds of good soft soap with gentle warming in 3 quarts of liquid carbolic acid (containing not less than 97 per cent of real tar acid). Mix the liquid with sufficient water to make 100 gallons.

* * *

Tobacco and Sulphur.—Steep 35 pounds of finely-ground offal tobacco in 21 gallons of water for four days. Strain off the liquid, and remove the last portions of extract by pressing the residual tobacco. Mix the whole extract, and to it add 10 pounds of flowers of sulphur. Stir the mixture well to secure an even admixture, and make up the total bulk to 100 gallons with water.

The time of immersion recommended is not less than half a minute, but a much longer time would seem to be necessary to reach the eggs and insects concealed near the roots of long fleeces or under hard scabs.

ELECTRIC CURRYCOMB.

Chicago has the latest—an electric currycomb. The Country Gentleman thus describes it:

To the ceiling are secured two small dynamos. From each long, flexible tubes depend, and attached to each of these is a small brush buzzing around in a dizzying whirl, after the fashion of the buzzers which seem to the victim in the dentist's chair like overgrown sawmills set at liberty. All the men have to do is to keep moving the brushes about, and with the invasion of each new portion of the animal's anatomy dirt and dust are sent flying from the hair of the horse. Both men and animal seem to be enjoying the experiment immensely.

Expert hostlers say it takes about twenty minutes to clean a horse with the ordinary currycomb, and about four with the electric brush.

No poor animal should be bred, as your increase only doubles your undesirable animals and retrograding is the consequence.

REMOVING WARTS ON HORSES.

I have read of a number of ways of removing warts, but have never read of my way. It is easy, sure and harmless. Make a strong string of harness or shoe thread, four or five strands, wax well together. Tie tightly around wart close to body. In a few days the wart will shrink. Then tie another string tightly back of that. Two or three times tying in this manner will effect a cure. The wart will dry up and drop off, leaving a very slight scar. I had a team of colts, one with a wart on shoulder where collar comes and the other had two large bleeding warts on face near the eye. I took them off in this way three years ago and they are all right yet.—Cor. Dakota Farmer.

INFIRMARY FOR HORSES.

With increasing number of hospitals for humans, it is not strange that dumb brutes are coming to demand similar rights for themselves till now it is quite common for horses to be taken to the hospital and may some day be as much so as it is for the human race.

It was our pleasure a few days since to visit the horse infirmary of Dr. Oliver, in the city of Los Angeles. Dr. Oliver has given advice to Cultivator readers as to treatment of diseases of stock and has been of much aid to many of our readers.

The infirmary in question is located at 318 E. Second street and is certainly fitted for handling the various troubles with horses or cows. The entire floor of the building is covered with a good cement paving, even to the box stalls, of which there are several, with every convenience for the comfort of the animals. Of course, the animals are not left upon the cement floor, but the entire surface of the box stalls are covered with a wooden grating which may be removed and the entire surface of the floor flushed off to the gutter which runs through the center of the building. In the rear, or the annex, is an operating table which is possibly common with the profession, but to the writer was a most interesting sight. It consists of a large, solidly built table, the top of which is on a hinge, and so constructed that it will turn from its horizontal position to a vertical, the edge of which reaches nearly to the ground. The horse is led alongside of this table, the top of which is vertical, and the various wide straps or webbing brought about the body and quickly fastened in an automatic clutch, all of which, when accomplished, binds the horse firmly to the table top. An attendant then steps behind the table and with a few turns of the crank the table top is lifted from its vertical position and tilted backward and in a very short period of time the horse finds itself firmly strapped, lying on the top of the operating table. This brings the horse into position, which makes any operation needed comparatively easy to perform. Some very skillful operations have been performed in Dr. Oliver's infirmary, which have saved the lives of valuable animals.

Be kind but firm with the bull. Handle him with consideration and a good stout ring in his nose. At times these tame fellows forget their bringing up, and then someone gets killed or crippled for life.

With nearly all the stock the profit is in breeding and feeding for quick growth and early maturity.

ABORTION.

This will continue to be a live subject with every dairy farmer for years to come. For if he has not felt its curse he does not know how soon he may. Meantime we can only continue to give every item of knowledge that promises, even in the least, to lessen the trouble. It was years before an efficient remedy was found for that dread disease, milk fever. Now no one who is well read dreads it at all. A writer in an exchange gives his experience with abortion as follows:

"I give each cow ½ oz. Calvert's No. 5 crude carbolic acid three times a week, or daily if necessary. Take the prescribed amount of acid, add a little glycerine, to make a perfect emulsion, mix with sufficient cold water to make a bran mash for each cow; then add the bran, mix thoroughly, and divide the mash equally among the cows. In some cases a cow will, for a time, take objection to the smell, and in such cases, I commence by giving her a quarter ounce or less.

All cows should be frequently injected with an antiseptic solution, say a three per cent solution, of Zenoleum. These injections should be given at intervals of a fortnight, during pregnancy up till within six weeks of calving. In any case where abortion is suspected to be in the herd, the bull should be carefully disinfected after serving each cow, by injecting the sheath with a disinfectant solution.

"I have also found excellent results, by carefully disinfecting the hindquarters of the cows, after milking, with a solution of creolin, 1 in 30 or the Zenoleum. This is easily done with a garden syringe, and is an excellent means of preventing the germs of abortion from entering the womb.—Hoard's Dairyman.

Fly time is at hand and a dark shed where the cattle can take refuge during the heat of the day is not only a humane provision, but the stock will take on more flesh for having it.

The letter E does not appear in the word "dairying" but it is the most important factor in the literature upon that subject. Witness the magic words breed, weed, feed.—Hoards.

The health of the sheep affects both the quality and the quantity of the wool.

VETERINARY DEPARTMENT

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease appeared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W. J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

LUMP JAW.

Editor Cultivator: I have a cow that is apparently in good health, but within the last few days I have noticed lump on one side of her lower jaw and it is growing larger. The lump is hard and seems to be fastened to the bone and as large as a teacup. Can give no cause for it. Kindly give remedy in Cultivator.—Subscriber, Pomona.

This is apparently a case of lump jaw, or actinomycosis, and is due to formation of peculiar tumors, usually on the jaw, though they may be on various parts of the body. It is caused by the growth of certain fungus. This disease has been observed for many years, in some cases has been confounded with tuberculosis. The course of the disease is quite slow and in this case where it appears on the jaw, will in time interfere with mastication. It is thought to be caused by the fungus being carried to the mouth through the food which, if injuring the membrane, may give lodgment for the spores of the disease, which in turn reach to the bone, and then the trouble begins. The animal should not be allowed to run with others not affected, though the chances of infection are very few. Treatment as given by Dr. Oliver is as follows:

Apply Churchill's iodine externally once a day. Give iodide of potassium internally, teaspoon twice a day.

BAD TEETH OR INDIGESTION.

Editor Cultivator: I have an eight-year-old mare, fairly valuable, has been gradually getting poorer, losing appetite for past month. Eats just enough corn fodder and green grass to keep her alive. Rarely eats any grain or bran. Most of time in pasture of Bermuda and alfalfa. She does not seem to have bad teeth nor, so far as I can see, anything wrong excepting loss of appetite and is hide-bound. Can you give remedy?—J. H., Santa Ana.

This certainly looks like a case of something wrong with the animal's teeth or with her mouth, though we note you say her teeth are all right. But Dr. Oliver suggests that you have the mare's mouth examined by competent veterinary dentist. He thinks you will find some abnormal condition which must be attended to. Give dessert spoonful twice a day of the following mixture: Tincture gentian, six ounces; Fowler's solution of arsenic, eight ounces; tincture nux vomica two ounces.

CLIMATE AND CROP REPORT

The weather and crop conditions for the week ending July 31 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—Clear weather prevailed during the week in the interior and foggy or partly cloudy weather in the coast districts. The temperature was slightly below normal.

Grain harvest is nearing completion in nearly all parts of the State and threshing is progressing rapidly. Barley is a good crop in most places, but wheat and oats are considerably below average and of inferior quality in many sections. They hay crop is the best for several years. Sugar beets have a high percentage of sugar and the yield is heavy. Beans and hops are doing well, but the yield of hops will be rather light. Corn and vegetables are making good growth.

Grapes are rapidly maturing and some varieties are in market; the outlook is good for a very large yield in nearly all sections. Fruit picking, drying and canning are in progress and considerable quantities of fresh fruit are being shipped. The yield of deciduous fruit is fair, though below average. Walnut blight is quite seriously affecting many orchards. Citrus fruits are in good condition.

Eureka Summary.—Cool, cloudy and foggy along the coast all the week. Crops are doing well. In the interior the weather was clear and warm; crops are suffering for moisture. Grasshoppers are doing considerable damage to vegetation on the highlands.

Los Angeles Summary.—The cool, cloudy weather is favorable for beans and root crops; it lessens the demand for irrigating water, but causes fruit to dry slowly. Orange trees are putting out heavy new growth; the fruit is still dropping, but prospects for a good crop continue.

Increase Your Profits
What's the use of trying to skim cream with a lot of pans or crocks, no end of hard, tedious work and then lose half to fully as much cream as saved? Or perhaps you use one of those tin-can affairs that borrow the name of "Separators" but forget to take along their results. Don't. There's a better way—easier, quicker, far more profitable, absolutely sure and perfectly safe. It's the "U. S." way.
DELHIE, MINN., June 6, 1905.
"I purchased a No. 6 U. S. Separator Feb. 1, 1905, and sold cream the first month to the amount of $52.52, the product of 8 cows. The month previous to getting the Separator the 8 cows produced me about $25. This herd of cows is about the average herd, three of them being heifers. I can heartily recommend the U. S. to all who want a first-class Separator.—H. A. DRYER."
110 per cent. increase! Pretty profitable investment, wasn't it? Yet only one of many thousands that prove the "U. S." way the most profitable. Isn't it worth investigating? That costs nothing. MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

FORCING THE MOULT.

(Continued from last week.)

When the Feathers Drop.—The change from the low feed to full rations will be followed by the rapid dropping of the feathers. The space under the roosts will be carpeted with feathers and they will be seen blown into the corners of the yard. The feathers will drop off all over the birds so that many of them will be almost naked. This result in forcing the moult will be seen in most of the birds. A few will fail to respond, more if you do not follow the plan outlined.

Keep the full feed up until the birds get the new coat of feathers and begin to lay a few eggs. Then feed them as you do the fully matured pullets, avoid overfeeding of heating food, lest you start another moult in the late autumn.

The birds that you are taking through the forced moult need to be well housed. They should have a tight roof over them at night, and a house that lets in fresh air in abundance, but without drafts of air. Cool fresh water needs to be given several times a day. Lice and red mites must not worry the birds. Sharp grit should be within reach at all times. If you wish to use the dry-feed hopper method of forcing the moult, it is easily done. Have three parts to the hopper. During the time you are reducing the flesh keep the hopper filled with bran, grit and charcoal. When you push the full feeding at the end of two or three weeks, fill the hopper with cracked corn, meat scraps, charcoal and grit. Do not neglect the green food and give good care to the moulting flock.

* * *

What About the Gain?—There is good money in the forced moult. No one more than the practical poultryman needs to use this method to increase his profits. Prices of grain are high and while eggs sell for good prices in the fall and winter, it is of no advantage to the hen man, unless he can get eggs to take to the market. Let the pullets do the best of your winter laying but do not neglect anything that will induce the older birds to have a good share in the profits of cold weather.

* * *

Treatment of Young Stock.—Reduce the flesh of your old stock of laying hens, along late in August. Having done this, feed for rapid growth of feathers. After they are feathered do not feed these moulted hens so much heating food as to the pullets. They will not stand so high feeding without getting over-fat and inactive. Lazy, too fat, yearling hens make very poor winter layers, and are second quality birds for spring hatching. It is only after they have set on one litter of eggs and got thin that they produce eggs that are worth incubating.

* * *

Put to the Test.—Dr. Sanborn ends this interesting article by saying: "I have used this forced moult for the last three summers with satisfactory results. This year I shall feed less in the first period, using little except bran and green food, and shall use the hopper method more exclusively than in the past years. I have an apple orchard for both hens and chickens. It is an ideal place for keeping poultry. The moulting birds would do very well in this orchard with no added food, but I never thought best to follow this plan. The results I have gained have been too good to try any other plan."

* * *

It is a great satisfaction to me to find that Dr. Sanborn, who is considered one of the best authorities on chicken breeding in this country, should so heartily recommend the plan which for the past two years I have outlined for the readers of the Cultivator for assisting the moult. I met a very intelligent gentleman a few days ago at Compton, who told me that he thought apples prevented hens from laying. I suggested to him that apples were only falling at moulting time and that it was probably the moult which affected the egg basket. I would like to call his attention to Dr. Sanborn's words that "for both hens and chickens it is an ideal place," speaking of his apple orchard.

The "dry feed hopper" method of which Dr. Sanborn speaks and which Dr. Nottage, Mr. Park, and many others approve is becoming more popular every year. It is simply giving the fowls their food dry. Some years ago a method of feeding called the "Sampson method," price one dollar for the formula, was largely advertised in the west. It was simply the ingredients of the mash mixed together without any liquid and fed in the morning. Then the hens had to eat it slowly or choke, they took a few mouthfuls and then visited the drinking fountain; at noon I gave them green food and at night a feed of grain. It was a fairly satisfactory method, but fed in open troughs a good deal of the food was wasted.

The more I study the "dry feed hopper" method and the longer I try it myself the better I like it. I am now feeding half grown chicks in this way, thorough-bred Black Langshans nad White Rocks, both from prize winners. I commenced with chick feed when the twenty-six were hatched, have not lost one; they are all great vigorous fellows, three months old. I killed one for dinner yesterday that weighed dressed over three and a half lbs. The dry feed I am giving them is two parts bran, two corn meal, two Calfalfa meal, one part Darling's beef scraps. I sometimes add one part of Kaffir corn, or one part of rolled barley.

"I must sell or give away all my hens," said a gentleman to me two days ago. "Why?" I asked in surprise. "Because my wife is going away and I have not time to feed them during her absence," he replied. I then described the Dr. Nottage plan of feeding the fowls once a week and I think he decided to try it. The only trouble he may have is in watering the fowls. Fowls drink about twice as much water and must have all they can drink when fed dry food. Next week I will discuss more fully the dry method of feeding in its various phases.

* * *

EDITOR'S QUESTION BOX.

A Good Layer.—P. G. W., San Jacinto): I have a standard bred Silver-Laced Wyandotte hen which commenced to lay January 15th last, and in the seventy-five days following she laid seventy eggs. During the six months ending July 15 she laid 145 eggs. Can you tell me how this record compares with other laying records? Also would it be advisable to mate this hen with one of her own chickens and if so, how old would the chicken need to be? We have found the poultry columns in the Cultivator of very great interest and value.

Answer.—You are to be congratuluated in having so splendid a layer; she is far above the average and by keeping her pullets and carefully watching their egg records you may build up a phenomenally fine strain of grand layers. I would, were I in your place, mate her to one of her most vigorous sons. He should be nine months old, or older if you have any older, and above all things do not let her run with any other male from this time on, even though you may not want the eggs now for setting.

* * *

Standard, Color, Etc.—(A subscriber): In an article in Cultivator on Line Breeding," you use the expression, "if they were up to standard." Please tell me how I may tell if mine are up to standard. I understand very little about chickens as yet.

Is color in Barred Plymouth Rocks an indication of "blood?" I have several pullets much darker than the cockerels, which are very light colored. Does that show that they are not thorough breds?

I want to line breed some of these, but having a few very fine White Leghorns I thought it would be better to cross-breed some of them. Would it not be better to use the Leghorn rooster with the Barred Rock hens than

HOW 1700 HENS BUILT A $3500 RESIDENCE

Story of a Southern California Poultry Farm

H. D. FREEMAN,
Santa Maria, Cal.

(By A. R. COULSON.)

On our automobile trip to Los Angeles, we found that there were several large poultry farms situated near Santa Maria, about four miles from town. As we were interested in seeing some of these large poultry farms we made a special trip out for that purpose. We first called on Mr. A. J. Freeman, who cordially received us, and made us feel heartily at home, and Mr. Freeman said he would take the afternoon off and show us the richest country in the world. So we took him, his wife and two children, in our machine, and we rode out for several miles to the new oil country, where we saw oil flowing in streams, and there were three large lakes of oil, as smooth as glass, and reflecting like a mirror. Whole lakes of oil, millions of dollars worth, and a little further up the mountains were two large gas wells, which were on fire, and the flames went up hundreds of feet in the air, and could be seen for many miles away, and they had been burning night and day for many months.

* * *

On our way back to the ranch, Mr. Freeman said we would go in and see his brother, Mr. H. D. Freeman, who is recognized as the largest and most successful poultryman of that country. Mr. H. D. Freeman was rather surprised to see us all, but welcomed us cordially.

Mr. Freeman invited us into his new residence, which is an elegant house of fourteen hard-finished rooms, eight closets, and cement cellar floor. His ranch covers 200 acres of good, rich land, and all surrounded with poultry wire netting fence to keep out all wild animals. He keeps 1700 laying hens, and for the past several years has kept books, recording the receipts from poultry, cost of feed, etc., and he showed us the books that showed how MANY MORE EGGS were laid, and how MUCH MORE THE RECEIPTS were the last year SINCE FEEDING COULSON'S FOODS, than they were for two or three years before, from the same number of hens. During the last year, from May 1, 1904, to May 1, 1905, the 1700 hens netted him a profit of over $2000.

* * *

EGG RECORD.

1700 hens fed one year on COULSON'S EGG FOOD. One meal each day. Started April 18, 1904. Eggs increased from 40 to 73 dozen a day.

Mo.	No. eggs.	Doz.	Amt. rec'd for eggs.	Rec'd P'ltry Sold
1904—

	195,970	16,331	$3633.36	$263.20

H. D. Freeman's new residence, 14 rooms, 8 closets and a cement basement; Cost, $3500.00. Built from the profits of 1700 laying hens (in 18 months time) which were fed on Coulson's Egg Food.

NOTE—During the last month, April, hens were only fed one sack a day of the Egg Food.

Amt. rec'd from eggs sold	$3633.36
Amt. rec'd from young roosters, etc	263.20
Value of eggs and poultry used in family	178.20
Total	$4074.76
Value of 510 sacks of Coulson's Egg Food fed	$ 892.50
Value of 577 sacks wheat, barley and corn fed	1115.20
Total cost of feed for year.	$2007.70
Net profit, 1700 laying hens fed one year on Coulson's Egg Food as per careful daily record	$2067.06

Scene on Freeman's ranches near Santa Maria. These fowls are all fed on Coulson's Feeds regularly.

NOTE—The poultry sold was young roosters, etc., fed with above supply of feed.

Figuring the value of wheat, oats and barley, at what they were worth if he was to sell it, as he raised his own grain (about 150 acres), his profits are really much more than as above stated, for raising his own feed, he did not have to buy much more than 510 sacks of Egg Food. He fed them 1½ sacks a day of it, excepting during the months of March and April last, he used but one sack a day and the hens averaged over two cases of eggs a day during these months. From now on, June 1st, he feeds them 1½ sacks a day for the morning meal.

During the past year he has put up fifteen new poultry houses, and also built a $3500 residence, which he moved into on April 25th. As the poultry has proved so profitable when fed on Coulson's Foods, this year he is raising several thousand more (they are fed on Coulson's Chick Foods), so that by fall he will probably have over 3000 laying hens.

Mr. Freeman's brother, Mr. A. J. Freeman, also has about 1000 laying

Freeman's White Leghorn Poultry Farm

Santa Maria, Cal. May 20, *1905*

Coulson Poultry & Stock Food Co.,
Petaluma, Cal.

Gentlemen:-

One of your salesmen was through here a year ago and I promised him I would feed Coulson's Egg Food for one year and keep a careful record of results and compare with former years. So I bought five tons of it to begin with, and on April 18, 1904, started to feed one and a half sacks a day of it, as the morning mash. At that time I was getting about 40 dozen eggs a day, but after I had fed it for ten days the hens began to increase, and by May 10th was getting as high as 73 dozen a day. During July, August and September they averaged from 25 to 40 dozen a day, whereas in former years, without your Food they would lay but very few eggs during the molting season,-one or two dozen a day being their average.

The record also shows for the months of October, November and December an increase of from 40 to 150 eggs per day over the previous year, with the same number of hens.

From May, 1904 to May, 1905, the 1700 hens have netted me more than $2,000.00 profits. I have put up fifteen new poultry houses and also built a new fourteen-room residence, into which I moved Apr. 25th. So you can see I have found it very profitable indeed, to feed your Egg Food, and I am now glad to place with you another order, this time for a carload of 15 tons, 330 sacks. My brother, A. L. Freeman and my neighbors Eames and Chaffin will take some of this car, so in a couple of months we will need another carload. The feed is all right.

Yours very truly,
H. D. Freeman

POULTRY RAISING A PROFITABLE INDUSTRY

The Freeman Farms

The Freeman poultry farms are the largest in the Central Coast counties. They use Coulson's Balanced Feed and make large profits.

hens, and he is now raising several thousand more little chicks on Coulson's Special Chick Food, so that by next winter he will have a much larger flock. He has also kept a record of amounts received from eggs sold for the past eight years, and SINCE FEEDING COULSON'S EGG FOOD, in comparison to the number of hens, THE PROFITS HAVE BEEN MUCH LARGER. His receipts from eggs sold show the same excellent results.

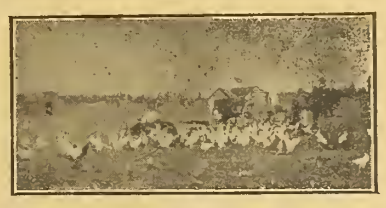
Mr. Eames, who has a ranch adjoining their farm, keeps a flock of 800 laying hens. He also has fed Coulson's Egg Food for one year, and has kept a record showing the increase over previous years.

Also Mr. Chaffin, another neighbor, has 600 hens, and has fed Coulson's Egg Food for more than a year, with marked increased profits from its use.

A 15-ton car of Coulson's Egg Food was shipped to H. D. Freeman on May 22d, and will be divided among these poultrymen, so that they use a carload of Coulson's Egg Food every two or three months.

For every dollar that you invest in Coulson's Egg Food, you will get back $3.00 worth of eggs. For every dollar ($) that you invest in Coulson's Egg Food, you should make $2.00 profit. Hundreds of poultrymen are making it and so can you.

A. J. FREEMAN,
Santa Maria, Cal.



Early morning scene on the Freeman ranch. Feeding Coulson's Egg Food.

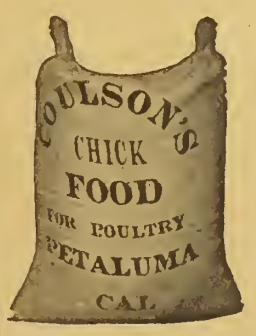
Those who are using $500 worth a year of Coulson's Egg Food are making in return more than $200 a year profit.

So remember that if you feed your fowls Coulson's Egg Food, the year round, that for every dollar ($) you invest in the food, you can make $2.00 profit in return, according to what others are doing.

Stay with the Coulson Food—feed it to your hens right along every day, for there is no better feed made.

You can buy Coulson's Egg Food and Coulson's Chick Foods from most any feed store; or if not, write to factory, give us name of your dealer, and we will send you a free Poultry Account book, as well as factory prices of Coulson's Foods.

Beware of imitations.



The Coulson Poultry and Stock Food Company

730-732-734-736 MAIN STREET (INCORPORATED. CAPITAL STOCK $100,000) PETALUMA, CAL

vice versa. My Leghorns were hatched the end of March and some of my Rocks the 10th of February. When can I use them for breeding?

Answer.—When I said "up to standard," I meant conforming to the description of fowls in the American Standard of perfection. The Barred Rock males are lighter than the females although the Standard requires them to be of the same shade. To get this breeders practice the double mating, keeping one pen to raise pullets and one to raise cockerels.

I think it a great pity to mix breeds as it gives nothing but mongrels. You will make more by keeping your stock pure.

Fowls hatched last spring will make good breeders next spring.

* * *

INDIAN RUNNERS, AND HOW I SAVED MY TURKEYS.

The following letter from one of our subscribers will prove very interesting and also may be useful to some of our readers:

"I feel sure that it will interest you to learn that one of my Indian Runner ducks, a daughter of those purchased from you, stole a nest a month ago, and today came out with five dear little ducklings. I believe from all that I have read that this is quite unusual. Another wants to sit, but it is so late in the summer that I am not giving her any eggs.

Another thing that may prove of intrest to you is the fight I made to keep a young turkey alive. He was chilled during a heavy, rain-like fog about ten days, or rather nights ago. He developed some difficulty in breathing, making a queer sound at every breath, and suffered from acute watery diarrhoea. He lay on the ground too weak to hold up his head some of the time. I first gave him six drops of whiskey and then a grain of quinine. I repeated the whiskey three times, at intervals of three hours and gave him another grain of quinine. I gave him a double dose of whiskey at night, but he was, if anything, worse in the morning. Thinking that nothing could save him, I resolved to experiment on him, so I rubbed kerosene all over his neck, breast, legs and under his wings, and gave him a teaspoonful of blackberry brandy, some little pieces of beef cut and forced down his reluctant throat, and then an onion cut in little strips. He would not swallow anything unless I pushed it past a certain point. Finding him still alive at noon, and at least no worse, I repeated the performance. As he seemed a shade stronger I repeated the treatment, keeping on this way for four days, and the fifth morning he came runuing up to be fed with the others, and has run everywhere with them and seemed all right ever since. As he was nearly half grown I could not bear to lose him. I do not know how the treatment would act on very young turkeys, but I think that the kerosene keeps out the dampness, and the blackberry brandy cures the diarrhoea. Of course if he had not been forced to eat he would have died from weakness.

I never raised turkeys before, and out of fifteen I had lost ten while very small from getting chilled on foggy nights, so I had determined to lose no more if doctoring and nursing would help me.

Answer.—Pray accept my thanks for your interesting letter. Indian Runners are considered as "non-setters" and usually desert their eggs when half hatched. About the turkey, it certainly was heroic treatment. I think the blackberry brandy was just the right thing and of course the kerosene helped, but was pretty severe; it will take all the skin off, just like a blister. I am very glad you saved its life; it just proves what I have often said that a good family medicine will have just as successful results with poultry as with human beings. In fact, if you can correctly diagnose any sickness amongst your fowls and use the same remedy as you would for the human family, you can be reasonably sure of success.

TESTING EGGS.

The farmer who sends his eggs to the market may be prone to think that the trials of producing them have been so great that they should be taken by purchasers without question and that the difficulties are all with him and not with the buyer. However, a few days ago, it was the privilege of the writer to watch the receiving and handling of a few cases of eggs in a large market house in Los Angeles, and it was quite surprising, the manner in which they were handled and how quickly the purchaser sized up the good, bad and indifferent eggs. Thinking possibly the producer might have a better understanding of the difficulties at the receiving end if we gave in the Cultivator a few words as to the condition of the eggs, we devote a little space to a description of what was there seen.

We may say that every egg in every case was tested with the result that a very large number of "seconds" and some that were so nearly unfit for use as not even worthy to go as "seconds" and others that were absolutely decayed were found. For instance, in a case containing thirty dozen eggs there are several dozen in the best of cases which will go as "seconds." Only one case in the day's run which we saw was marked perfect. The tag on this case showed thirty dozen first-class eggs. There were no "seconds, no "rots," no "shorts." The dealer told us that nearly every case which came in was short one or two or more eggs. All during weather such as has prevailed for the last few weeks, there were a few "rots" and almost invariably many "seconds."

Now the question may be asked, what is a "second?" In fact, that is a question which we asked the dealer, which led to the privilege of going into the testing room. He promptly asked us to "come this way" aud we were at once ushered into a small dark room in which the operator stood before a little box in which were two holes, nearly as large as a small egg and behind these holes were incandescent lights, those being the only lights in the room. The operator picked up two eggs, one in each hand, before the small holes. He determined instantly whether "firsts," "seconds" or "rots" and by a quick finger motion the two which had been inspected were dropped back into the palm of the hand and the other two brought forward and placed against the holes. The strong light, shining against the eggs, allowed him to determine at once the quality of the egg. If clear and no cloudiness appeared, they went into the "firsts." If a "floater," that is, the yolk had separated from connection with the white, by a quick turn of the egg he was enabled to determine by the appearance of the strong light. If the cloudiness was very pronounced then it was put with the "rots" as unfit even for baker's cooking. Some of the eggs which were shown to us were so badly decayed as to be absolutely opaque.

We asked the dealer what was the real condition of the "floaters" when broken and one was promptly broken and turned out on a piece of cardboard, when the yolk broke and ran over the board with the white of the egg, neither of them having any body and being more like water than a good, healthy egg. Such eggs as that are perfectly good for bakers' or general cooking purposes, but making a poor showing when used for poaching or general table use. The vast number of "seconds" at this time of the year makes them much lower than the 'firsts," for the reason that in the winter, when there are few of them, the bakers desire to get them as cheaply as possible, leads to picking them up so rapidly that they fall but slightly below the price of "firsts," while now the quantity is so great that the bakers realize they can get them at almost their own price and they fall four or five cents and even more per dozen below the regular quotations for "firsts."

We asked the dealer as to the lowering of the grade on these eggs coming in as they do and he said there were various reasons. Sometimes the farmer is careless in gathering but more often the time between the purchase at the grocery and reaching the market during the hot weather was sufficient to lower the grade. It was also influenced by the section from which the eggs came. For instance, at the present time he said there was great trouble with eggs from the Imperial valley and the San Joaquin valley. In both sections, the heat has a bad effect upon the eggs before they can possibly be gotten into the market.

He who waits to do a great deal of good at once will never do any.—Johnson.

America produces eggs to the value of three hundred million dollars a year. All the cattle and hogs slaughtered annually in this country are worth less, and so is the country's total annual output of both gold and silver.

Queries and Replies

PEACHES.

Editor Cultivator: Kindly give the name of one or two good cling peaches and also a free stone; that is, the peaches the canners prefer and the best priced fruit. Also what kind of root the young trees ought to have. Some say a certain kind of root brings more fruit and also the borers don't like them.—S. L. S., San Jose.

There are several good orange clings, each similar and as a rule all good. The lemon cling is a good shipper and canner. The Tuscan, or Yellow Tuscan, is exceptional in quality, ripening with Early Crawford free stone. The Phillips is sometimes said to be preferred by canners to all others. It is later than the Tuscan.

In free stones, the Crawfords, Lovell, Foster and many others are good. The Muir is excellent as a drier, but not acceptable at cannery.

WEEVIL.

Editor Cultivator: I wish to learn of the process or method to preserve beans and peas from the attack of bugs while in the dry state or during the drying. I have tried some remedies suggested to me in past years without success. I notice that seedsmen keep their seeds.—E. F. B.

Doubtless our subscriber refers to the weevil which is a pest in many sections, especially south of Tehachapi. Late planting avoids much of the damage to growing crops, but we assume the inquirer is troubled more with pest in the dried product. For that the most successful treatment is placing in closed room and saturate the atmosphere with fumes of carbon bisulphide. If only a small quantity are to be treated place in jar or tub and close tightly after putting in small quantity of the bisulphide. Use great care to have no light nor fire about, for the stuff is most inflammable.

WHO IS THE CHAMPION?

Editor Cultivator: As many hundreds in California are now engaged in apricot work, it will be interesting to learn who has the right to claim the championship for apricot pitting.

We here in Fremontville claim it for Mrs. Chapman and her two daughters. On July 27 they pitted, in 10 hours' work, 92 boxes of 50 pounds fruit in each. As this lady is rather faster than her two young daughters, she had forty boxes to her credit. Can this be beaten or even equalled by any of your readers?

The 27th was record day in our little drier for the season. Besides the three ladies mentioned, the daughter of the house pitted 27, two sisters of fourteen and fifteen years old, fifty together. Two yard men thirty boxes; in all 199 boxes for eight pitters, or an average of 24⅞ boxes for the whole pitting crew.—M. W. P. Wright, Fremontville, Ventura county.

NEW PROCESS OF COOLING FRUIT

From an interview with A. R. Sprague in the Sacramento Union, we note the following regarding the new process of cooling cars of fruit before starting on their long eastern journey:

"The trial developed several things. It settled conclusively in the minds of all present that that is the proper method for the initial cooling of fruit, since in four and one-half hours of continuous running the car was left in excellent condition to go forward under regular refrigeration.

Some problems presented themselves in adjustment of the machine and the proper distribution of the cooling current to secure the best results in least time and also a question as to what temperature it is necessary to obtain in order to secure the best results in fruit shipments.

It will take some careful experiments to determine these various important points and I propose to work them out with this and similar machines at other points. After spending a few minutes in an iced car freshly loaded with fruit at a high temperature and closed up no one would afterward wonder that so often our unripe fruit even breaks down on its way to the East. Although the blower was applied to the car as soon as iced, the air drawn from the car was already suggestive of decay. Soon, however, all these gases were condensed in passing through the cold chambers and the air moving in the car was as fresh as a sea breeze. This, I am inclined to think, is of greater importance than a very low temperature of the fruit.

The theories of the slow movement of air under ordinary conditions do not at all apply when it is under pressure suction in a carload of fruit. Experiment only will determine this phase of the question.

The machine will be in continuous use with the cars of the California Fruit Exchange at Loomis, and when the method of using it to secure the highest efficiency is ascertained, the fruit growing and shipping public will be fully informed of such methods and results."

DEEP ORCHARD CULTIVATION.

(Continued from First Page.)

tached and one good deep furrow laid as nearly as possible over the subsoiler furrow. As the water follows this furrow, it naturally drops into the lowest depth of the line opened up by the subsoiler and not only following down to the lower end of row, but also breaks through sideways in the cross furrow made by the subsoiler. When the water reaches the bottom of orchard, that the roots of the trees have received a thorough drenching goes without saying. Just as soon as possible to get on ground afterwards, the smoother is passed over and the ditches filled so as to cover the moist soil with dry dirt as soon as possible. Later comes the deep cultivation which every orchard should have and more are getting nowadays than formerly.

These irrigations are given every six weeks, though this year the trees have received but one up to the present time and, though the day of our visit was quite warm, not a single leaf indicated any desire for water and the fruit was all of large size, indicating it had never suffered for water.

After the irrigation season closes, when the ground has become somewhat dry and hard, then another subsoiling is given, more likely furrowing diagonally through the orchard, so as not to strike the same lines which have been followed during the summer irrigation.

Mr. Wuest's neighbors had little patience with his method of work and one of them informed him that $1000 would not hire him to permit such tearing out of roots as he had given to his orchard. But sure it is the appearance of the orchard, which has never been fertilized excepting once with light dressing of commercial fertilizer and once with stable manure, indicates that the trees are not now suffering from want of fertility in the soil. Mr. Wuest said if he was to fertilize and had his choice, he would by all odds prefer the stable manure to the commercial fertilizer. But one warning he gave, and which we mention right here, though not exactly in the line of this article, and that was never to use manure from stables which bedded the animals with planer's shavings, and to show the force of his remarks he asked us to walk across the orchard where some especially heavy soil needed some "lightening" up. On that section of, as we remember, anywhere from fifty to one hundred trees, he had placed a large quantity of planer shavings. He said as a mulch it was magnificent and as some worked into the soil it seemed to work up far better and hold moisture prefectly, but while it was four years since this was done, that plot of trees could be outlined perfectly by their yellow and unhealthy looking condition. He said all other treatment since that manuring had been identically the same as with the rest of the orchard and only those trees on which the shavings had been put showed the yellow cast and refused to bear large crops of fruit. Therefore, he concluded, the only solution of the problem was that the redwood shavings had that which an orange tree, at least, did not like.

But to return to the question of tillage; allow us to quote from one of the old-time books on manures, by Harris. In that we note:

"Sir John B. Lawes has somewhere compared the owner of land to the owner of a coal mine. The owner of the coal digs it and gets it to market in the best way he can. The farmer's coal mine consists of plant food, and the object of the farmer is to get this food into such plants, or such parts of plants, as his customers require. It is hardly worth while for the owner of the coal mine to trouble his head about the exhaustion of the supply of coal. His true plan is to dig it as economically as he can, and get it into the market. There is a good deal of coal in the world, and there is a good deal of plant food in the earth. As long as the plant food lies dormant in the soil it is of no value to man. The object of the farmer is to convert it into products which man and animals require.

Mining for coal is a very simple matter, but how best to get the greatest quantity of plant food out of the soil, with the least waste and the greatest profit, is a much more complex and difficult task. Plant food consists of a dozen or more different substances. The three substances most difficult to get at are: nitric acid, phosphoric acid and potash. All these substances are in the soil, but some soils contain more than others, and their relative proportion varies considerably. The substance which is of the greatest importance is nitric acid. As a rule, the fertility of a soil is in proportion to the amount of nitric acid which becomes available for the use of plants during the growing season. Many of our soils contain large quantities of nitrogen, united with carbon, but the plants do not take it up in this form. It has to be converted into nitric acid. Nitric acid consists of seven pounds of nitrogen and twenty pounds of oxygen. It is produced by the combustion of nitrogen. How is organic nitrogen converted into nitric acid? It is brought about through the action of a minute fungoid plant. There are several things necessary for the growth of this plant. We must have some nitrogenous substance, a moderate degree of heat, say from seventy to one hundred and twenty degrees, a moderate amount of moisture and plenty of oxygen. A water-logged soil, by excluding the oxygen, destroys this plant."

That tillage is manure is one of the oldest saws of the science of agriculture. In fact, the original meaning of the word "manure" was "hand labor." "To cultivate or enrich by manual labor." The ancients, knowing the beneficial effects of stirring and admitting air to the soil, expressed it as manure as applied to hand tillage, which was afterwards applied to the dressing which was put upon the ground which, by accident, an ancient soil tiller discovered auswered the purpose to a certain extent the same as the ordinary "manure" or hand labor. Now we are prone to go to the other extreme and think the word applies only to a dressing of fertilizer applied to the surface of the soil, and, at the same time, think that tillage is simply keeping down weeds and preventing loss of moisture. Meantime there is, in ordinarily rich soil, anywhere from a ton to a couple of tons of each of the three elements most necessary and most expensive. Approximately a hundred pounds of each is all that is required for a crop. Then let us make available the natural, stored up wealth in our "coal mine," or better, our gold mine, for coal is of little value in this country. That one of the greatest essentials of converting these elements into available plant food is plenty of oxygen; and that to get oxygen into the soil, deep cultivation is necessary we believe is more and more realized by soil culturists.

It is estimated that the loss to the apple crop of this country from the codling moth reaches at least $20,000,000 annually.

A MATTER OF SELECTION.

Said a little vulgar girl who was sneering at another
In accents that were very far from mild,
"You ain't got no father, you ain't got no mother,
You ain't nothin' but a horrid 'dopted child!"

"I'm quite as good as you," came the answer from the other,
"I was carefully selected from a lot;
But only look at you—your father and and your mother
Had to keep you if they wanted to or not!"

THOSE EVENING BELLS.

Those evening bells! those evening bells!
How many a tale their music tells
Of youth and home, and that sweet time
When last I heard their soothing chime!

Those joyous hours are passed away:
And many a heart that then was gay
Within the tomb now darkly dwells,
And hears no more those evening bells.

And so 'twill be when I am gone—
That tuneful peal will still ring on;
While other bards shall walk these dells,
And sing your praise, sweet evening bells.

—Thomas Moore.

A Bag of Money.

"The old man is going to New York tomorrow night with $10,000."

"How is he going?"

"By boat."

"That makes matters easy."

"Who's going to do the job?" asked the first speaker.

"Perhaps it would be well for two of us to go."

"And the two best at that."

Four men were holding the above conversation one evening in the sitting room of the man who spoke first! they were a gang of robbers of the "better class," if I may use that term in connection with stealing. In order to hold themselves above suspicion and gain valuable information they were all employed in Boston business houses of the most respectable character.

Their employers had every confidence in them, and each had dealt with every cent personally intrusted to his care in a perfectly honest manner, thereby proving himself trustworthy.

Another rule was that booty taken should not be investigated except in the presence of the four. Even in the trade of robbery there can be a sort of honor.

Louis Crawford was chosen to head this job.

"Twenty-five hundred apiece; not a bad sum. Disguise yourselves well and take no risks. You know the old man's habit of taking his money in that bag I took the pattern of," said the victim's secretary, Minot Ware.

"Don't give any more directions, our own mothers wouldn't know us twenty-four hours hence. Just hand over that pattern bag and let us go home and to sleep if we are going to be out tomorrow night," said Crawford.

The next afternoon Mr. George Cobb sent for his secretary.

"I am going directly from the office to the train tonight, and I want you to stay a bit later than usual and take my bag down; in fact I wish you would go all the way with me and do that business for me in New York tomorrow morning."

"Certainly I will go. It would be a pleasure," replied Ware, inwardly congratulating himself that he should be able to covertly assist his partners.

"Thanks, a few hours from you in the morning will save an important day for me, and you can be back here by tomorrow night."

An Avenue of Fan Palms.

"Do you see that old man over there," asked Mr. Cobb, when the train had started.

"The man with the long white beard?"

"Yes; he was on the last time I came this way and we got quite friendly; he comes from where I used to live in Maine and goes to see a son in New York."

Mr. Cobb was so fortunate as to get his Maine friend to sit on the deck with him after supper.

Ware saw them comfortably settled and then proceeded to search the boat for his partners; secret signs were given with no result, and finally he gave up the search.

When Ware returned to the two men, the old man had Mr. Cobb intensely interested in news of his old home, and the secretary fairly felt like improving the opportunity himself, but just then there arrived on the scene of action a fourth man, who was introduced to Mr. Cobb as Mr. Sykes.

An effort to interest Mr. Cobb on the part of these two men was successful, and with a few clever transfers the deed was done and Mr. Sykes walked off with the $10,000 bag.

"This my bag?" said Mr. Cobb, as they prepared to part for the night.

"It is not mine," replied the old man as he took up his own.

The four men gathered the next evening in their room, and Staley brought out the bag they had taken the night before, as yet unopened.

"You did that little job well, just as I was beginning to think you were not there," said Ware.

"Think we would forget that $10,000 in that little time?" said Staley, as he opened the bag.

"He has not raised the cry of 'stolen' yet."

"Strange, I expected to hear it on the boat this morning and see it in the papers this afternoon. We transformed ourselves and the bag, expecting something of the sort."

"What's the matter Staley? Can't you get the cash? You seem to be having a hard time of it."

"Well, now, I am. The old man had it well wrapped."

"We can afford to have patience," said one, taking a comfortable attitude.

"By George! He has got it done up in a hundred papers," said Staley, as he proceeded to take off one wrapper after another from the bundle he had finally managed to get out of the bag.

They thought each new one he took off must be the last, but there was always one more until the package left in Staley's hands was nothing more or less than a well worn pocketbook.

"It must be big bills," said one.

But the opened pocketbook contained only a scrap of paper on which they read:

"Dear Friends—I am not a fool, I always carry large sums in checks. Keep this bag, with my compliments—also the pocketbook.—George Cobb."

And the date was some ten years previous, which showed how well prepared Mr. Cobb had been for many years.

NONE LEFT TO CHLOROFORM.

"Shall we chloroform the old folks of the next generation?" asked the sage of Plunkville.

"If cigarettes an' tight lacin' keep their present holts on the respective sexes," retorted the Pohick philosopher, " there ain't goin to be no old folks in the next generation."—Pittsburg Post.

London has one licensed drinking place to every four hundred and forty-six inhabitants.

"Oh, my friends!" exclaimed the orator, " it makes me sad when I think of the days that are gone, when I look around and miss the old familiar faces I used to shake hands with."—Modes and Fabrics.

Cookery Recipes

Cooked and Poached Eggs.—Anything can be spoiled in the cooking and nothing more easily than eggs. As a matter of fact, eggs should never be boiled. When served in the shell, they should be well covered with boiling water, placed where the water will keep near the boiling point for five or six minutes.

Poached eggs should be dropped in boiling water, well salted, covered closely and set back to cook slowly.

To cream eggs, grease a hot spider over with butter, put in a half cup of cream, break in the eggs, cover closely and cook very slowly.

* * *

Poached Eggs on Rice Toast.—Boil half a pint of rice in three times its bulk of water, so that when done all the water will be absorbed; pack into a square tin and set away over night. The next morning cut into slices an inch thick, fry brown in melted butter, and serve with a poached egg on each slice.

* * *

Chocolate Tapioca Pudding.—Soak a half-cup of tapioca over night, drain, pour on boiling water enough to cook it till clear. Add three-quarters cup of sugar, a tiny shake of salt and two ounces of shaved chocolate. When the chocolate is well mixed with the tapioca, add the well-beaten whites of two eggs, stir in lightly—do not beat it, then add a half-teaspoon of vanilla extract, pour it in a dish and set aside to cool and serve with cream.

* * *

Sparkling Lemonade.—Roll and slice half a dozen lemons, put in a large pitcher and pour over one gallon of ice water; sweeten. Pour in glasses and stir in a little soda.

* * *

Shrub—Mash a gallon of ripe red currants, or other small fruits; pour over a pint of strong vinegar and a quart of cold water; let stand five hours, strain and add a pint of sugar to a pint of juice; let boil and skim; when cool bottle and seal. A few spoonfuls added to a glass of ice water forms a very cooling, palatable drink.

* * *

Gherkin or Cucumber Pickle—Take two hundred small cucumbers; cover with cold water, to which add a pint of salt. Let stand over night. In the morning drain off the water, measure and take as much vinegar as water, one ounce each of whole cloves and allspice, and a piece of alum the size of a walnut. Boil the vinegar and spices and pour boiling hot over the cucumbers. Cover with cabbage leaves. A few green peppers in the vinegar give an added flavor and are a great improvement.

Another process for the same pickle is the following: Soak the gherkins in a brine composed of six ounces of salt to a quart of water for twenty-four hours; drain and dry thoroughly with a cloth; pack in jars; pour over them vinegar, allowing for each quart of vinegar one ounce of salt, one-quarter ounce of black pepper corns, one ounce of ginger, two blades of mace and a dozen bay or parsley leaves. Let stand for two days, then put all in a preserving kettle and let simmer gently until well cooked. Replace in jars and seal.

A mind content both crown and kingdom is.—Robert Greene.

HOMELY HINTS.

Nothing takes the soreness from bruises and sprains as quickly as alcohol.

A teaspoonful of lime water will cure colic.

In case of a burn wet the injury and then apply flour or soda. It forms a paste and keeps out the air.

* * *

Filling Cracks in Floors.—To fill cracks in floors around the skirting board, or any other part of a room, neatly and permanently, soak newspapers thoroughly in a paste made of one pound of flour, three quarts of water and a teaspoonful of alum, boiled and blended. The mixture will be about as thick as putty and may be forced into the cracks with a knife. It will harden like papier mache.—The Housekeeper.

* * *

Cleaning Compound.—For cleaning highly polished furniture, take 1 tablespoon of raw linseed oil, 1 tablespoon turpentine, 1 tablespoon soap and 1 quart boiling water. Let boil ten minutes. Stir occasionally to mix thoroughly. This mixture can be used warm or cold but is more effective when warm. Apply with a soft flannel well wrung out to a small portion of surface to be cleaned at a time. When dirt has been well wiped off, polish with a fresh flannel.

REMARKABLE WORKS OF HUMAN LABOR.

Nineveh was fourteen miles long, eight miles wide, and forty-six miles round, with a wall one hundred feet high and thick enough for three chariots abreast. Babylon was fifty miles within the walls, which were seventy-five feet thick and one hundred feet high, with one hundred brazen gates. The temple of Diana, at Ephesus, was four hundred and twenty feet to the support of the roof. It was one hundred years in building. The largest of the pyramids was four hundred and eighty-one feet in height, and eight hundred and fifty-three feet on the sides. The base covers eleven acres. The stones are about sixty feet in length and the layers are two hundred and eight. It employed 320,000 men in building the labyrinth in Egypt, and it contains three hundred chambers and twelve halls. Thebes, in Egypt, presents ruins twenty-seven miles round, and contained 350,000 citizens and 400,000 slaves. The Temple of Delphos was so rich in donation that it was plundered of $50,000,000, and the Emperor Nero carried away from it two hundred statutes. The walls of Rome were thirteen miles around.

USES FOR PAPER BAGS.

In every household should be kept on hand a collection of the paper bags that are used by grocers for wrapping provisions, for they are most convenient for many purposes. A supply may be purchased, or those in which clean groceries, like sugar, eggs, etc., are purchased, may be smoothed out, and put away for future use, in a pasteboard box, where they will remain clean, and free from dust.

They are not only for wrapping various articles that must be sent or carried away from the house, but are actually useful for saving work, and keeping things clean. Slipped over the jars of preserved fruit, and jelly tumblers, when they are first filled, the contents will be kept perfectly dark; more than this, when one is ready to open a jar, it can be taken out of the bag, and will be found clean and free from dust. It is much less work to open a can that is clean, than to handle one that is covered with dust, and must be sponged off, before it can be touched with any comfort.

It requires a scouring to remove the dirt that gathers on the tops of jars each winter, if the new set of preserves are to have bright covers. All this work is avoided by the use of the bags.

A collection of thick paper bags of medium size should be kept for shielding the hand when a stove must be cleaned. Whether it is a coal or gas range, slip the right hand into a paper bag before grasping the cleaning cloth, and the condition of your nails will not require half an hour's work, after the stove is clean.

The whisk broom and all sorts of small brooms and brushes that are used in a kitchen, or for cleaning, about a house, will be kept free from dust, and last longer, if they are slipped into a paper bag when one is done using them. If a whisk broom is used for sprinkling clothes, it should be kept away from all dust; the flatirons too, should be placed in paper bags, and laid away in a dry place. It is trifles such as these that insure the perfection in laundry work that is no trifle. If one hasn't the usual bag made of ticking, clothespins can be kept put away in a stout paper bag, where they will be kept perfectly clean. Rubber bands will hold these bags in place and sometimes a mere twist is sufficient.

In country homes, where kerosene lamps are used, clean paper bags turned over the chimneys, after the lamps are trimmed each morning, keep the glass free from dust and steam, and one has a clear chimney when the lamp is lighted.

These are but a few of the uses to which these bags may be put, but in every home, there will be ways to use them which will become apparent, when the housewife discovers how really useful they are.—Vick's.

TO BE CONSISTENT.

It is reported that the Vegetarian society of Massachusetts has prohibited its members from marrying any woman who is not a grass widow.

CURED.

A woman who lived in Racine
Was fearful that she would get line,
So she drank lots of water,
As thin people ater,
And now she's as round as a bine.

Instructor (at night school)—What are the chief curses of American civilization?

Shaggy-Haired Pupil—'Bout the same as the English, only we use 'em more freely in our common talk than they do. You don't expect me to blurt 'em out, do you?—Chicago Tribune.

Music Teacher—Johnny is improving daily in his violin playing."

Johnny's Mother (gratified)—Is that so? We didn't know whether he was improving, or we were just getting more used to it."

I've allus noticed great success
Is mixed with troubles, more or less,
And it's the man who does the best
That gits more kicks than all the rest.
—James Whitcomb Riley.

"When you have leisure," said a caller to the city editor, "I would like to speak to you." "All right; come after I'm dead."

Why are two young ladies kissing each other an emblem of Christianity? Because they are doing unto each other as they would men should do unto them.

If you would be strong, conquer yourself.

Man should be ever better than he seems.

THE CLEAT ON THE BOX.

Regarding the engraving which appeared in Mr. Shoemaker's advertisement last week, showing advantages of the patented cleat which he uses in all his shipments, there has been some little interest since that issue of the Cultivator so that we refer again to the cleat and the good which it may accomplish.

Mr. Shoemaker says that all his shipments go forward under this arrangement, which he has taken a patent upon and he offers this as an advantage to his patrons who may ship their oranges through him. Or sell to him, rather, for, as probably noted in his announcement in last week's Cultivator, he is now prepared to place next year's oranges on a purely cash basis. We understand Mr. Shoemaker has had wide experience in both the East and at the shipping end and understands oranges and the demands of the consuming public as few other dealers do. As he said, he has marketed over five hundred cars this year, with several months yet to clean up the season, in which he will ship several more and these shipments have been to the satisfaction of the producer.

But, more particularly, does he make his strong point on the use of the cleat which relieves the pressure of the tight pack without squeezing the life and shape out of the fruit in the press. In illustration of this point, Mr. Shoemaker has a number of photographs taken from boxes of fruit on arrival East, one box having been shipped under the patented cleat, the other the ordinary "tight pack," as usually sent out. The difference between the two, even in a small photograph, is most apparent, because of the much larger showing of decay in the box without the cleat. The fruit in each case was from the same packing house, shipped in the same car, had the same ventilation and general treatment from start to finish. As Mr. Shoemaker said, it is simply a case of more squeeze for the delicate fruit of the one box which started to rot first.

Regarding this plan of protecting the fruit from the extra pressure, Mr. Shoemaker can show any number of most complimentary commendations from fruit buyers in almost every fruit buying center of the country. One buyer in Baltimore, Md., says:

"We wish to write you and compliment you on the extra cleat that you use on your boxes; we have found that this holds the fruit very steady, and the fruit seems to fill the boxes to much better appearance."

A large buyer in Dayton writes: "There isn't any question but that the fruit will arrive in better condition and we know the fruit will sell much better."

From farther away Montreal the cleat is also favored, for the largest fruit buyer there writes: "Nothing but praise to offer—not only protects the fruit, but gives the box a better and larger appearance—the buyers here are delighted with it, as they are sure that no damage to the top row of oranges could be done—they always prefer buying your package."

Any fruit grower who may be interested in receiving the largest returns for his year's labor may get some valuable information by getting in touch with R. H. Shoemaker, who may be addressed at 522 Hellman Bldg., Los Angeles.

Los Angeles Markets.

Los Angeles, August 2, 1905.

Butter.

Butter stands at exactly the quotations of last week but with market very firm, owing to the fact that supplies are short of the demand and storage is drawn upon nearly every day to meet the trade requirements. Arrivals of Eastern are rather light.

The United States Honey Report of 1899 shows California produces 170 cars of honey; Texas 220 cars (marketed mostly at home); New York 160 cars; Missouri, 140 cars; Iowa, 120 cars; Kentucky, 180 cars; Illinois, 135 cars; Colorado, 81 cars; Arkansas, 65 cars.

San Francisco Markets.

San Francisco, August 2, 1905.

DAIRY.

Under slight demand the butter market is somewhat weaker and shows a decline of a couple of cents during the week. There are, however, light holdings of better grades which compels top quotations for fancy stock.

BUTTER—Per lb:

Creamery, fancy	23 @24
Creamery, good to choice	21@22
Dairy, choice	20
Store	17 @18

CHEESE—Per lb:

Cal. Creamery, mild new, ex.	11
Do, choice	9 @10
Young American	12 @13
Eastern, N. Y., Cream	17 @18

EGGS.

The demand for eggs continues vigorous, causing a satisfactory increase in quotations. Selected ranch are very scarce and readily command top quotations.

EGGS—Per doz:

Ranch, selected large	29 @30
Ranch, good to fancy	26 @28
Store	18 @22
Eastern extra	22 @23
Eastern firsts	19 @20
Eastern, seconds	17 @18

POULTRY.

POULTRY—Old Roosters, per doz., $4.50@5.00; young Roosters, $4.50@6; Fryers, $3@4.00; Broilers, $2@2.50; Hens, small, $4@5; large, $5.50@6; Live Turkeys, per lb., 18@20c; Spring Turkeys, 23@25c; Ducks, old, $3.50@4; young, $4@4.50; Geese, per pair, $1.50; Goslings, $1.50@1.75; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $1.50@1.75.

FRESH FRUITS.

Apples, per box, fancy, 85c@$1; common to choice, 40@75c; Crab Apples, per box, 65c@$1.

Apricots—Per box or crate, 65c@$1; bulk, per ton, $35@40.

Figs—Per box, $2@2.50.

Pears—Per box, Bartlett, No. 1, $1.50@1.75; common, 75c@$1.25; bulk, per ton, No. 1, $60; No. 2, $25@40; other varieties, per box, 50c@$1.

Peaches—Per box, 35@60c; carriers 60@80c; basket, 40@50c; open boxes, 40@75c; bulk, per ton, Freestones, $30@35; Clingstones, $50@60.

Plums and Prunes—Per small box or crate, 50@85c, as to variety; bulk, per ton, $10@15.

Nectarines—Per crate or box, 75c@$1.

Grapes—Per box or crate, Seedless, 65@85c; Fountainbleau and Sweetwater, 50@75c; Muscats, 65@75c; Blacks 65@75c.

Cantaloupes, per crate, River, $2@3; Watermelons, per doz., $1@3; Nutmeg Melons, 75c@$1.25.

Blackberries—Per chest, $1.50@3.

Raspberries—Per chest, $5@7.

Strawberries—Per chest, Longworths, $3.50@6; large varieties, $2@4.

Huckleberries—Per lb., 7@9c.

VEGETABLES.

VEGETABLES—Tomatoes, per box, 25@40c; Green Peppers, per box, Chile, 65c@$1; do, Bell, $1@1.50; Okra, per box, 75c@$1; Garden Beans, per lb., Green, 4@6c; do, Wax, 4@6c; Lima, 6c; Garden Peas, per lb., 3@4c; Cucumbers, per box, 35@50c; Pickles,

per box, 35@60; Egg Plant, per box, $1@1.50; Garlic, per lb., 3@4c; Green Corn, per sk, $1.50@2; per crate, $2@$3.

ONIONS—Per sk, Yellow, 85c@$1.10.

POTATOES—Per ctl.: River Burbanks, 40@85c; Salinas Burbanks, 85c@$1; Early Rose, 40@50c; Garnet Chile, 40@55c.

DRIED FRUITS.

The market on prunes seems to be in a most excited condition with offers to sell very light. Some holders of Santa Claras are demanding 3¾ cents basis. Offerings of peaches light, with market strong, ungraded sacks selling readily at 6½ and 7 cents. Apricots firmer.

Peaches—1905 crop—Crawford, fancy, 7½@7¾c; choice, 6½@7c; standard, 6¼@6½c; Muirs, fancy, 8¼@8½c; choice, 6¾@7½c; standard, 6½@6¾c.

Prunes, 1904 crop—Sack basis, f. o. b.: For boxed goods add ¼@½c; 40s to 50s, 4¼@4½c; 50s to 60s, 3¾c; 60s to 70s, 3¼c; 70s to 80s, 2¾c; 80s to 90s, 2½c; 90s to 100s, 2c; 100s to 120s 1¾c; 1905 crop, 3¼@3½ basis for Santa Clara four sizes; other sections ¼c less.

Apricots, 1905 crop—Royal, fancy, 7¾@8c; choice, 6¼@7c; standard, 5¾@6c; Moorpark, nominal.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c, choice, 3¼c; standard, 2¾c; ungraded, 3½c.

HONEY AND BEESWAX.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

HOPS.

The price of desirable stock is nominal at 24@27½c per lb, according to quality, many producers demanding thirty cents.

LIVE STOCK.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@5½c; rough heavy, 4¼@4½c; common, 3½@4c.

HAY AND FEEDSTUFFS.

HAY—Per ton: Wheat, $9@13.50; Wheat and Oat, $8.50@12.50; Oat, $7.50@11.50; Barley, $7@9; Clover, $7@10; Alfalfa, $6@10; Stock, $5.50@7.50.

New crop Wheat, $9@13.50; Oat, $5.50@11; Wheat and Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $21.50@22.50.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@28.50.

OATS—Good to choice, White nominal; Red, $1.20@1.35 for new crop; Black, nominal.

CORN—Good to choice, per ctl: California, new large Yellow, $1.45@1.47½; small do, $1.55@1.62½; White $1.37½@1.42½; Eastern Yellow, $1.40@1.45; White, $1.40@1.45; mixed, $1.40.

RYE—Good to choice, per ctl., nominal; new, $1.47½@1.50.

CITRUS MARKETS

In oranges there is but little to report in the way of a change from last week's conditions. The auction markets, if anything, are somewhat stronger on Valelncias, the prices being very satisfactory and somewhat higher than the prices received in Western markets. The West is taking practically everything enroute in the way of desirable sizes at full prices and the conditions are very favorable under well regulated shipments for a continuance of the satisfactory results now being received.

The lemon market is about the same as reported last week. The demand being rather light in the West, but shipments are not heavy and with good demand for California lemons in the eastern section prices have remained firm on both our stock and foreigns. There are two large cargoes still to sell and some small lots, and no further shipments of large amounts are expected from the other side, so that the situation is strong and very satisfactory.

NEW YORK.

The market at New York was in fair condition during the last week. Weather was cooler than for some time, enabling the handler to keep fruit in better condition. The general market was such, however, that any large offering would soon have upset conditions and caused a reducing of prices. Prices which prevailed generally from the store were from $5.00 to $5.50 for fancy Valencias; $4.50 to $4.75 for choice.

Grapefruit was in better demand than for some time, though large quantity of poor fruit held the market down from what it otherwise would have been.

Owing to cooler weather, lemons declined, showing practically a fifty cent lower quotation than for the week prior. They sold at $5.00 to $5.50 for choice 360s; $5.50 to $6.00 for extra fancys. Extra fancy 300s went as high as $6.35.

Monday's auction was lighter than ordinary, only five cars being offered. This tended to steady prices and Valencias held full top quotations. Other varieties not wanted as a rule. Most sales are made in small quantities, usually from ten to fifteen boxes. Lemons continue scarce and high, with sales very active from store. Valencias brought from $4.20 to $4.75 for the better grades and $3.00 to $4.00 for the lower grade stock, even many standards bringing as high as $3.50. One lot of California lemons sold at $4.75.

Two cars of Valencias were the total of the citrus sales of Wednesday. Market was somewhat stronger, extra fancy bringing as high as $5.55. Standards even commanded $4.45.

Lemons firmer.

BOSTON.

Only one car Valencias sold at Wednesday's sale. Market stronger. The $5.00 was the highest reached, Standards selling at about $4.00. No lemons offered.

CITRUS SHIPMENTS.

Total since November 1st, 28,283, of which 3547 were lemons.

BEARING THE HOP MARKET.

There seems to be a systematic effort on to lower the price of hops and unfortunately some growers have been led into accepting below any probable legitimate market which may prevail during the coming season. Many have combined and agreed not to sell one pound of hops before August 1st, under thirty cents per pound and it is claimed these have kept the faith and are still holding. Many others have sold at twenty-six and twenty-seven and some have become so scared at the efforts of the "bears," who are claiming that even fourteen and fifteen cents a pound will be reached before the season is over, that they are selling at almost any price.

Regarding the probabilities of this exceedingly low price, the Sacramento Union says: "If the United States grows 250,000 bales, England 600,000 cwts., and the Continent a full crop, we may see hops selling at 14 to 15 cents—not less. The chances that these things will all happen are about as one to fifty. The outlook at this time is reported as favorable for England. But that means very little.

Last year, predictions were made of great output in other producing sections and hops started at fifteen cents in June. From that day they rose to seventeen and nineteen cents by the middle of the month and by the middle of August to twenty-five cents.

"These facts go to show how futile it is for anyone, particularly a dealer who wants prices to go low so he can stock up or "cover," to try to make growers believe that a bumper crop and low prices are imminent.

The best informed man in the trade knows no more what will be the outcome during the next sixty days than does the novice."

REMOVAL.

While down on Santa Fe avenue a few days since, we found a state of confusion bordering on cyclone-destruction appearance in the factory of the Yucca Manufacturing Co. Inquiry soon developed the information that the big new two-story building which was pointed out to us a couple of blocks below is to be the future home of this old standby manufactory. So it is with pleasure that we announce the removal of this company to their new building, 2124 Willow st. This new building is a substantial, well built frame building, two stories in height, the upper one of which will be used for the drying of the yucca productions of the factory, while the lower will be for the machinery and the offices. The building heretofore occupied has been the property of the company, but was on leased ground, while now the company occupy their own property entire and feel a greater degree of comfort in its occupation. We are glad to see the prosperity manifested by this company, for it is one of the old-time friends of the orchardist of California, in that it was the manufacturer of one of the original appliances for tree protection.

We are informed by Mrs. Aiken, of the Bamboo Poultry Ranch, that the new hatch in the mammoth incubator is progressing finely, especially the section of it devoted to ostrich eggs. This is a new departure of this big incubator, for contract has been made with the Cawston Ostrich Farm to hatch the eggs of that institution. Mrs. Aiken also informed us that she has applied for a patent upon the idea of the 'dobe incubator which she hopes to secure, for she says she has been working for many years upon this idea.

IN WOMAN'S BREAST

ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

THREE PHYSICIANS OFFER $1000

If They Fail to Cure Any Cancer

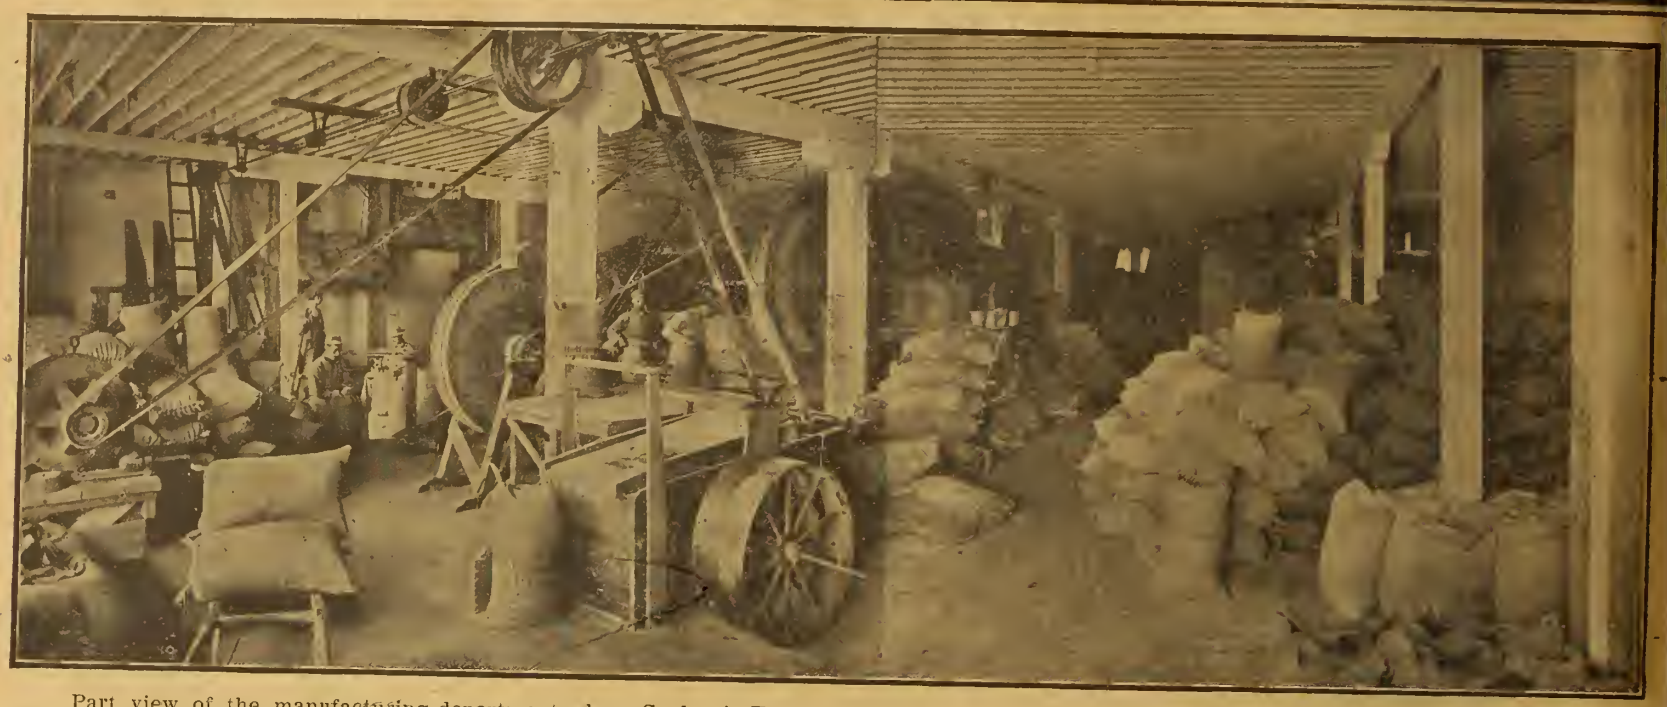
SCENES NEAR HERBEYLI, ASIATIC TURKEY

Shaking a Smyrna fig tree to cause such figs as have not fallen of their own accord to drop. In this section is found the home of the fig and near here Mr. Roeding studied Asiatic methods and secured the insect, Blastophaga grossorum, which has made fig culture successful in California.

The lower engraving shows the knocking off of Smyrna figs which have not fallen when at the proper stage of maturity, with poles of the giant reed, Arundo Donax.

CIRCULATION EXCEEDING 10,500

THE MAKING of a SUCCESSFUL POULTRY FEED



Part view of the manufacturing department where Coulson's Egg Food and Coulson's Chick Food are made. Notice solid stone floor. See the men at work bringing the different feeds and ingredients to the mixing machine. Thousands of sacks are handled daily. There is one pile containing over a thousand sacks of Armour's Meat Meal. Another pile of sacks of fine ground Bone Meal. Another pile of three thousand sacks of shorts. Another of fifteen hundred sacks of flour middlings. In another place you will notice a carload of Armour's Dried Blood. In another, eight hundred sacks of fine ground beef scraps. In another pile a carload of ground oats. and in another a stack of two cars of granulated corn meal, and back in the corner sixty thousand pounds of Minnesota Millet Seed, car lots of Cracked Rice, steel cut Oat Meal, different seeds, etc. There are tons of charred bone Charcoal, and barrels of powdered Willow Charcoal. and big stacks of many other ingredients.

OUR SPECIALTY—MAKING GOOD FEED.

John D. Rockefeller's specialty is oil, Andrew Carnegie's, steel; Senator Clark's mining. These men were and are specialists. They organized themselves to excel, just as we have organized ourselves to excel in the manufacture of the BEST FEED for POULTRY. It is the one thing we think of, dream of. and talk of. When a man's heart is set on his task, he does it better than the "don't care fellow."

We do not and will not employ any one who is not interested in their work, consequently we repeat to you that we make GOOD FEED FOR POULTRY, (none better but lots that are worse, we assure you.) Making GOOD FEED for poultry is our specialty. and we have got it down to perfection. We manufacture a feed that will make your hens lay, as you never dreamed of before. Not only is the feed good to make hens lay, but it helps the fowls and it also gives them richer blood and keeps them in healthier conditions.

Being specialists in the line of mixed poultry feed, we can give you the best feed at the lowest prices.

All fowls over two months old, pullets and laying hens should have one meal a day of Coulson's Egg Food as a warm mash. Feed it for one year and see what there is in it.

It takes several weeks to show any great gain in egg production on any change of feed. Many poultrymen have tried Coulson's Egg Food for a few days and given it up as a failure, while there are hundreds and even thousands of poultry keepers who have fed Coulson's Egg Food for over a year's time and have made the greatest of success. and who feed Coulson's Egg Food every day to their hens. and every day they get plenty of eggs.

TWO HUNDRED HORSE-POWER ENGINE.

That runs the machinery which grinds up the bones for making fine ground bone meal, and pulverizes the charred bones for making Bone Charcoal. Etc.

These ingredients are used in making Coulson's Egg Food (a mixed food for pullets and laying hens) and Coulson's Chick Food, which are mixed by machinery and mixed properly.

The healthiest looking fowls, with bright red combs, are those that are fed on Coulson's Egg Food.

TRY IT FOR ONE YEAR.

Experience, backed by the general law of average, proves that feeding any change of food for the first week or two doesn't bring results. A trial of a SACK OR TWO is a waste of money. If you GO IN. stay in, and it WILL PAY YOU. "Keeping everlastingly at it" is the ONLY WAY TO SUCCESS.

MR. POULTRYMAN, there is only one way to buy, and that is on record of WHAT YOU WANT. If you want to make a good record, buy good feed. Character is a man's record. So it is with feed. Buy on character. When you buy Coulson's poultry foods you buy on character, and get a standard article of feed that contains only the best and wholesome ingredients.

Rumsey, Cal., Dec. 15, 1904.

This is the first season I have used Coulson's Egg Food and I find it excellent for the purpose. Since feeding it I have had more than double the number of eggs that I ever have had before from the same number of hens.

Yours truly,

A. A. HENRY, Rumsey, Cal.

The Process of Fig Curing in California

Described by Geo. C. Roeding, Who Has Devoted Years to the Study of This Fruit, Both in This Country and in Europe

Varieties.—The only white fig which has been used for drying purposes on an extensive scale in California, is the White Adriatic. There is no denying the fact that this fig is of inferior flavor, although at the time of its introduction twenty years ago, it was predicted that it would equal the imported Smyrna fig in flavor. Years of experience have demonstrated that this fig makes a very inferior dried fruit and no matter how it is manipulated can it be made to compare with the imported fig. It is the only variety produced in quantities in California today, having any commercial importance. This fig has done so much harm to the fig industry of the State that dealers in the East scoffed at the idea of California ever producing a good fig and when the Calimyrna was introduced it was very difficult to convince the jobbers that this was a distinct fig and fully equal to the imported Smyrna fig. It is not within the province of this article to take up the relative merits of these two figs. The very fact that the Calimyrna and Smyrna have been conceded to be one and the same thing by experts, established its superiority.

In addition to the two varieties mentioned there is the Mission or California Black Fig, for which there has always been a limited demand. The only point against this fig is its color. The skin of this fig when properly dried, is soft and pliable, and the pulp, although having a sweet and pleasant flavor, lacks the distinct quality of being rich, therefore there is no possibility of its ever becoming an important factor in the fig business.

The fruit business of California has not been cradled in a bed of roses, but has been fostered by men who have been compelled to realize that the article offered for sale must be equal in flavor to a similar one, which has been imported for years from Europe. The fruits of Europe are held up as a criterion, and unless we can offer something equal or superior our claims for recognition are sure to be ignored.

* * *

Locality.—The acreage adapted to fig culture in California covers such a great area that it is not necessary to mention any particular locality or localities. Figs for drying purposes, and that is the manner in which they will be consumed, can be grown wherever the temperature does not go lower than 18 degrees Fahrenheit above zero in winter and where the summer temperature is from 80 to 110 degrees. Another important point is the necessity for a dry atmosphere, a condition which is found from San Diego to Shasta, fifty to sixty miles inland. The fig adapts itself to a great variety of soils, and such varieties as the Mission, White Endich (a pickling fig) and the Calimyrna, none of which are subject to souring, one of the objectionable features of the White Adriatic, can be grown where the water will stand close to the surface during a good part of the season. Such soils, however, are not to be recommended for fig culture.

The three varieties of drying figs will be considered in the order they have been referred to.

* * *

Drying Adriatics.—The White Adriatic commences to ripen its figs from August 10th to September 25th, and the season is even later than this in some years. The figs are never picked from the trees, but are gathered from the ground in tin buckets as they drop. If the figs are slow in falling, the trees are shaken severely and all mature figs as a rule then drop to the ground. The figs have reached their full stage of ripeness when they hang limp and seamed on the tree. After being gathered, they are dumped into picking boxes, holding from forty to fifty pounds of fruit. The work of gathering the fruit is in many cases done by boys, who are paid from $1 to $1.25 per day, or they gather by the box, receiving ten cents per forty pound box.

A small one-horse truck is used for carting the figs around and after enough are gathered, they are hauled to the drying ground. An old alfalfa field or one covered with wild grasses, something to keep down the dust, is best adapted for this purpose. In addition to the defects already mentioned, the White Adriatic is not uniform in color, and as the trade demands that a white fig must have a white appearance the figs are exposed to the fumes of sulphur from one to three hours. The time of exposure and the quantity of sulphur to be used is readily determined by the operator. If exposed too long, the figs will when dried taste of the sulphur fumes very strongly and the fruit will have a sickly white color, an indication that they have been in the bath too long a time. The figs are either sulphured in pickling or sweat boxes, which are half filled. Before putting them in the boxes they are sprinkled with water. Slats are placed between the boxes as they are stacked so as to permit the fumes of the sulphur to permeate freely through the fruit. Never take the figs out of the sulphur house late in the afternoon as they will invariably turn dark. Far better to put in a small quantity of sulphur and allow the figs to remain over night. The figs after being sulphured are spread on trays 2x3 ft., and are turned every other day until dry. An empty tray is placed on a full one and by a dexterous twist of the hands the figs are transferred to the empty tray.

The proper stage of desiccation is indicated by taking the figs between the fingers in the morning before the sun is up and if the fruit feels leathery and somewhat firm to the touch it is dry enough.

The time of exposure varies from three to four days, according to the weather, but time should not be taken into consideration, for whenever the fruit is dry the working between the fingers determines the fact. All beginners make the mistake of over drying. When this occurs, all the saccharine matter has been extracted from the fig and it consists of nothing but seeds and a hard, thick and tough skin, rendering it practically useless for commercial purposes.

The figs should not be dumped into sweat boxes (a sweat box is eight inches deep, two feet wide and three feet long) until they have become heated by the sun. The boxes should be filled up and the figs pressed down tightly, as this causes them to go through a sweat and equalizes the moisture throughout and also softens the skin. Before hauling to the packing house the fruit is washed in a cold brine, made by dissolving three ounces of salt to the gallon of water. They are then spread out on three by six foot trays with two inch cleats all around, to allow the moisture collected from washing to dry off. The washing removes all dirt which has collected during the course of drying and the floaters which arise to the top are taken out and used for hog feed. Then

(Continued on Page 138)

A TEN-YEAR-OLD CAPRI FIG TREE.

The wild fig which retains its hold upon the fruit through the entire winter, thus affording a home for the Blastophagus throughout the year. The framework shown was constructed to afford a support for covering to protect from cold. This was used as an extra precaution, for fruit on other trees not protected have never been injured by Fresno's coldest weather. The trees in the background are those of the edible or commercial Smyrna variety.

The Pineapple in Hawaii

A Former Owner of the California Cultivator, now a Planter near Honolulu, Writes Entertainingly of the Culture of the Pineapple

Many old time subscribers of the Cultivator will recall the names which formerly stood at the head of the Cultivator as its owners and editors were "Goodwin and Thomas." Several years ago Mr. Thomas severed his connection with the paper to join a colony going to the Hawaiian Islands, on the Island of Oahu, some twenty miles north of Honolulu, to engage in horticulture. The growing of pineapples proving most profitable that industry now predominates in the colony. When Mr. Thomas visited California a few months ago he promised an article, which promise he now fulfils and we trust it will be of interest not only to our subscribers in Hawaii, but to those in California. We are sure the older subscribers will be glad to hear again from Mr. Thomas.

* * *

Editor California Cultivator: Wahiawa is the settlement started in 1899 by half a dozen families from Los Angeles and vicinity, who came here just after the islands were annexed to the United States and bought a tract of land from the government. Previous to their occupancy the land had been leased as pasture, had never been cultivated, and was considered unfit for agricultural purposes by the old timers. This year there will be harvested over half a million pineapples from this land.

The first two years the Californians did a lot of costly experimenting with miscellaneous farm crops, vegetables, etc. Fortunately however, among the fruits planted soon after coming onto the land were several thousand pineapple plants of the Smooth Cayenne variety, and in about two years they bore a crop of magnificent fruit. Good judges and old timers said such fine pines had never been seen on the islands before—both as to size and quality. As there appeared to be a good market for such fruit, the question what to plant was at once settled and everybody began planting all the plants they could buy. The price of plants was about $25 a thousand—some paid more—and the supply on the islands limited. However, every one got enough to start them and now there are over a million pineapple plants growing at Wahiawa.

A great deal of the fruit is shipped fresh to the coast, but the bulk is sold to the cannery, located in the center of the tract. The cannery's pack this year will be about 20,000 cases of pineapple. We are in the midst of our summer harvest now, and every one is busy. There are two crops a year, from about June 15th to October 1st, and from December 1st to March 1st. The winter crop, however, is only about one-fourth as large as the summer.

After the fruit forms the plant sends out from one to three suckers and usually from one to half a dozen slips. One or two suckers are left on the plant and they produce fruit in twelve months and the balance are taken off and planted. The latter will mature fruit in from eighteen to twenty-four months. An average of three or four plants can be secured from each mature fruit. That is how plantations can be extended so rapidly.

The growers have not been in the business here long enough to have arrived at one opinion as to the number of plants to put on an acre. All plant in rows, two feet between each plant, but the distance between rows varies on different plantations from eight feet to two feet, and the number of plants on an acre from 2700 to 10,000. The wide planting will permit rattooning profitably for a longer time—possibly three or four rattoon crops—while one rattoon is all the close planting will stand, when the field will have to be plowed up and replanted. A year or two more will decide fully which will produce the greatest number of pounds of fruit in a given time.

(We take it that Mr. Thomas means by "rattooning" the allowing of growth of suckers about the parent stem year after year, after removal of fruit of former year, thus necessitating great spread over the ground and ultimately growing several pineapples at one time on each root. Or, more correctly, perhaps, each rattoon ultimately has a root system of its own, for, we believe, the offshoot comes from below the surface and sends out new rootlets.—Ed.)

Mr. Thomas' Pineapple Plantation on Oahu Island.

Many of the growers know all about growing oranges and other fruits in California (I guess I had better modify that, as, judging from the discussions I see in the Cultivator about orange growing, even the old-time Riverside growers have a great diversity of opinions as to which is the best way to handle an orange grove. As I was saying, several of the pineapple growers here spent years in orchard work in California, but their experience did not avail them much with pineapples, and the only pine plantations on the island were a few small ones owned by Chinese near Honolulu.

Among the prominent growers here is Byron O. Clark, formerly of Pasadena, who the old-time subscribers of the Cultivator will remember as a regular contributor to that paper. Another is A. W. Eames, who for many years carried on an extensive nursery business in West Los Angeles.

For the benefit of those who do not know how a pineapple grows (and I find there are many) I will say that they do not grow on trees nor under ground, as I have heard ordinarily intelligent people say they thought they did. They grow a single fruit on a plant, about two feet high, with a spread of spikes or leaves about the same. The Spanish Bayonet, so common along the foothills of Southern California, very much resembles a pineapple plant, and the fruit grows up from the center of the plant. It takes about four months from blossoming to ripening of the pine.

So far no serious pests have developed to interfere with their growing. That cannot be said of many other crops on these islands, however, and Prof. Koeble, Alexander Craw, and several others are kept busy. Strict laws have recently been passed to prevent the introduction of harmful insects not already here and when the Board of Agriculture secured the services of Mr. Craw as superintendent of the Division of Entomology they got the right man to enforce them.

A reservoir with a capacity of two and a half billion gallons is being built at Wahiawa, to store storm water for irrigation. H. Clay Kellogg, of Santa Ana, is the engineer in charge, and his brother, L. G. Kellogg, formerly of Los Angeles, is manager of the water company. The cost will be about $250,000.

Oriental labor is employed almost exclusively on the islands. There are 61,000 Japanese, 20,000 Chinese and several thousand Koreans and Porto Ricans. The total population of the islands is about 150,000. The Chinese are considered the most desirable and it was a serious blow to the planters when the exclusion law went into effect here. Some of the sugar plantations employ over 2000 laborers and pay them from $18 to $20 per month, with free house rent, fuel and medical attendance. Before annexation they paid $12 per month. That is not all. Uncle Sam has collected over four and a half million dollars customs receipts since annexation, which before, went into our own treasury. A pretty big price to pay for the privilege of being a territory of the United States, but if congress would only vote the money for the much needed fortifications and the improvement of Pearl Harbor, so much talked of since annexation, no one would complain.—W. B. Thomas. Wahiawa, Oahu, Ter. of Hawaii, July 18, 1905.

(Mr. Thomas refers only incidentally to irrigation, that is to the building of a storage reservoir, but from conversation with him when he was on the Coast last summer, we know that regular irrigation is necessary. The water has been supplied from a stream passing through the tract, but doubtless extensions of plantsing has created need for storing additional water.)

THE COUNTRY WHERE THE WIND BLOWS AND OTHERS.

When Kansas can get as much comfort from their cyclones as is indicated by the following clipped from the Kansas City Star it is time for Californians to brace up and be content—Content with a big C.

It is noted that there are no tornadoes or cyclones north of the 50th parallel. When you get up around Canada and Nova Scotia, there is not enough hot air to mix with the cold air to make a decent whirlwind in the road.

But even with the memory of Marquette and Snyder fresh in your mind, please don't jump at the superficial conclusion that it would be grand to live in a country where the wind never goes waltzing around in the form of a funnel. Just pause long enough, before packing your traps for Manitoba, to take a cursory inventory of the things you would miss in leaving Kansas or Missouri, and the price you would have to pay in purchasing immunity from cyclones and tornadoes.

There are plenty of other things besides wind funnels that are not found north of the 50th parallel. No cantaloupes and watermelons, mind you, gladden the bleak hearts of Canadians; no green corn on the cob; no pawpaws; mighty few, if any, fresh cherry pies; not nearly enough spring lamb and new peas to go around; plenty of oats, we grant you, but as Doctor Johnson wisely observes, oats is a cereal eaten by men and women in Scotland, and by horses in England; wheat by the train load, to be sure, but isn't there a "right smart chance" of wheat in Kansas and Missouri?

With spring garden truck just coming on, don't get excited about the country north of the 50th parallel. Just rig up a cyclone cellar or a cave and stay with the melons and the green corn and the pawpaws and the other good things in God's country."

Lichen cannot adhere to trees that have been thoroughly washed with washing soda and soft soap.

BEEKEEPING FOR BEGINNERS.

There is something very interesting in the matter of quality in regard to the various kinds of food. The Ben Davis apple sells because of its fine appearance. All lovers of good apples acknowledge that it is very inferior in flavor, yet a friend said to me the other day, "Give me a Ben Davis of all apples." He was from Missouri, where the Ben Davis is much grown. A taste built up on Grime's Golden, Northern Spy and Spitzenburg could hardly understand his position. Those who have been brought up from their youth where maple syrup is produced have learned to appreciate the syrup made from first-run sap when all the apparatus is sweet and clean, especially if made rapidly and with the utmost painstaking. Such syrup is almost as white and clear as water and has a flavor that can hardly be described, it is so delicate and exquisite. I was speaking of this at the table of a friend only a day or two since, when he remarked that he did not like that kind of syrup. He preferred a darker kind and the pungency which goes with it. I thought of him as of the advocate of the Ben Davis apple, "There is no accounting for tastes."

We find similar experiences in matters of honey. While those of cultivated taste who are wonted to the very best that the culinary art can give us, much prefer, and praise only the lighter grades of honey, like that from basswood, clover, alfalfa, white and black sage, and the mesquite, yet there are others, and I have known not a few such, who prefer and always select the dark honey when they can get it. Such people prefer the flavor which is always present in the darker grades of boney. I have one friend, a college professor and long a colleague who always preferred buckwheat honey and laid in his supply in the late fall when he could get this kind. While I was glad to supply him this, I always laughed at him and expressed surprise at his taste. The golden rod honey and other honey from the autumn wild flowers in the East, though not quite as dark as that from the buckwheat, are highly colored and somewhat pungent in flavor. Here belongs the amber honey of our wild buckwheat of California. While most will prefer the white grades of honey, and others who will prefer honey of the darkest hue, like buckwheat, the wide-awake beekeeper will be on the sharpest lookout for customers, especially of these latter classes, for thus he may gain a market for all kinds of honey at good prices. If a person thinks that buckwheat honey is the best, or if he prefer the amber colored honeys, he will make no objection to paying the best market price for honeys of these grades. The friend I referred to above never objected to giving me a first-class price for buckwheat honey? Indeed, it would hardly be consistent to claim that a honey is first-class or of the best quality and yet request that a lower price be asked for it.

Another point of interest in this relation has to do with the grading of honey. The up-to-date beekeeper will see to it that his honey is kept by itself, for this will always bring the highest figure in the market. Later in the season, as the bees commence to gather from sources which give amber colored honey, the whiter grades will all be extracted that the amber honey may be kept by itself. In this way the grade of the lighter honey will not be lowered. In California the beekeeper cannot be too careful in extracting to keep his sage and alfalfa honey entirely separate from that from the wild buckwheat. It is even more important that the still darker buckwheat honey be kept by itself. It is hardly necessary to suggest that these darker grades of honey are just as suitable for wintering the bees as is any that is produced. Thus it behooves the beekeeper to extract the lighter honey and let the bees fill up the combs with the darker varieties in the later part of the season, for their own food during the winter.

With the beekeeper, as with those in any department of agriculture, it is important to grade carefully. There are few points which the beekeeper should study with more thoroughness than that of grading. If he is producing extracted honey he has only color to guide him in making up his grades. If, on the other hand, he is working for comb honey, then he must have a lookout not only for color, but for the number of uncapped cells, completeness of the sections and the general appearance of the same.

* * *

KINDS OF FRUIT TREES TO SET.

While visiting Mr. E. A. Gammon at his very profitable fruit farm on the Sacramento river, a few weeks since, I asked him what fruits he would set were he going to set a new orchard. His long and very successful experience makes him an authority in these matters. He replied that if cherries did well and there was little danger of the ground being flooded, he should give a prominent place to this fruit. In his section the cherries have been prolific bearers while the great demand for this fruit always insured a good price. A portion of Mr. Gammon's farm was flooded last winter. It was found that the cherry trees were largely destroyed if the water stood for any considerable time in the orchard. Next to cherries, Mr. Gammon would recommend the Bartlett pear. The pear is a very heavy producer, this fruit almost always brings a good price in the market and the trees have showed their ability to withstand the effect of flood to a remarkable degree. In reply to the question of danger from the ravages of blight, Mr. Gammon replied that he expected to be able to keep it down by free pruning and the liberal use of disinfectants. He added, with a twinkle of the eye that was suggestive, that many would not do this careful pruning and so he expected to keep his orchard and have less competition. Mr. Gammon also had found good money in peaches and apricots, but believed them much less profitable than the above varieties.

* * *

DISINFECTION IN PEAR BLIGHT.

Those who have studied closely the suggestions of Prof. Waite for protecting against pear blight will remember that he not only urges that the branches be pruned a good distance back of the injury but that the pruner should always carry with him a dilute solution of carbolic acid, and should sponge liberally his pruning instruments and the cut limbs as he works to eradicate the fungus from his orchard. I believe that the orchardist (and I may add the beekeeper as well, in the case of foul brood) cannot be too cautious in this work of disinfection. We must all remember that in all this work to eradicate bacterial diseases, we are fighting a very insidious foe, and we cannot be too cautious in all our work that we may stay the spread of the germs.

It has been my pleasure the last few days to be in company with one of the most distinguished and successful surgeons of the United States. He has a wonderful record. I asked him to what he most attributed his phenomenal success. He answered, "Caution in preventing infection." One seeing him at work in his own hospital can but appreciate and greatly admire his painstaking care to fence against the wee bacilli. It would be well if the beekeeper who has to fight foul brood or the orchardist who is contending against the plague of pear blight could spend a few days with this eminent surgeon that they might learn the nature of the foe with which they are contending and the extreme care requisite to success.

* * *

THE ARSENITES.

Mr. Gammon, whom I have referred to several times of late in the Cultivator, asked me at the time that I visited him, why it was that I, with others, continued to recommend Paris green as an insecticide. Like all our best orchardists, Mr. Gammon is a thorough believer in the use of the arsenites for the codling moth and against all leaf eating insects. If there were nothing better, he would certainly use Paris green. The Kedzie mixture is made by boiling together soda and white arsenic. Mr. Gammon says that this is not only much cheaper but much safer and much more easy of application. I would advise all our fruit growers who have occasion to use the arsenites to refer either to the Berkeley or Washington bulletins on the various arsenites and try this Kedzie mixture.

A friend of mine once told me that he was losing millions of dollars by not being able to have enough cattle to eat all the grass which then grew on the open prairies. Untold wealth is going to waste by not being able to have bees enough to gather the sweets from the flowers that bloom in season. A few colonies of bees will help any farmer to increase his income if he takes kindly to them.—Iowa Homestead.

WALNUT TRADE IN HUNGARY.

According to report the walnut crop of southeastern Europe this year will be very weak, as spring frosts caused great damage in the chief places of production. Hungary will have to import and the prices "ab station" will be even higher than 40 crowns ($8.13) per 100 kilos (220.46 lbs.)—Report of F. Dyerchester, U. S. Consul, Hungary.

WALNUTS IN CHILE.

One variety of walnut is grown in Chile, the amount of a normal crop being 30,000 to 40,000 bags, gathered in February and March. The estimated crop for 1905 is 20,000 to 25,000 bags. Quality better than last year; 90 to 95 per cent of the crop is exported principally to the Argentine Republic, east coast of South America and the United States. Present price is $14 Chilean gold per 44.16 kilograms (96 pounds). Freight rates to New York and to Europe 45 to 50 shillings per ton.

VALENCIA RAISIN CROP

Improved methods in cultivating the Muscatel vine have resulted this season in the most abundant crop on record. Estimates are for a yield of 600,000 cwts., against 432,000 cwts. last season. Lower opening prices are generally forecasted and some of the most sanguine exporters are even expecting prices to enable them to successfully compete with California growers on American markets. On the other hand, stocks in foreign hands are reported almost cleared and those held by home speculators barely reach a total of 10,000 cwts. First shipments will be made early in August.—J. L. Byrne, U. S. Consul, Valencia, Spain.

DEMAND FOR INFORMATION.

The Horticultural Commission has continuous demand from outside sections for its literature which is regarded as of especial value in all fruit growing districts of the world. Regarding the extent of this demand we note the following regarding one day's calls, in the Union:

Yesterday in one mail Secretary Isaac received requests for reports to be forwarded to Palestine, the Cape of Good Hope and Assiniboine. Not before have there been calls for California official reports from such widely separated points at one and the same time.

The republic of Mexico, in its Department of Fomento, has a bureau of Parasitlogia which corresponds to our Department of Horticulture. News has been received that this deparlment has translated into Spanish the California Horticultural Commission's bulletin on the orange for circulation in Mexico. It has also ordered translated for publication Mr. Isaac's report on the orange maggot.

The strawberry bed is a good place for all the ashes that can be produced on the place. It drives off the insects and fertilizes the plants.

NEW HORTICULTURAL PUBLICATIONS.

The State Horticultural Commissioner has just issued two very valuable bulletins, one on the Russian thistle and the other a compilation of all the State laws and county ordinances bearing on horticulaure. The last session of the legislature passed a law making it part of the duties of the County Horticultural Commissioners to see that the Russian thistle and other noxious weeds were eradicated in their respective counties. As the Russian thistle is not prevalent in California, this law has caused a great deal of inquiry and very many weeds have been mistaken for it. It is for the purpose of supplying the necessary information in regard to this pest that the present publication has been issued, and the descriptions given there, together with the illustrations, are so full that there will be no excuse for anyone not recognizing this weed when he sees it. The bulletin on the county ordinances and State laws will also fill a long felt want on the part of the County Horticultural Commissioners, nurserymen, tree dealers and others who come under their operations. Nearly all the fruit counties of the State have ordinances supplementing the State laws, and these differ in many cases, making it difficult for shippers to know how to conduct themselves. The present bulletin gives all in a nut shell. Either or both of these publications can be had on applications to the State Commissioner of Horticulture, Sacramento.

THE SEVEN AGES OF A TREE.

A very practical way of classifying trees according to size is the following: Young trees which have not yet reached a height of three feet are seedlings. They are called seedlings in spite of the fact that any tree, of whatever age, if it grew from a seed, is properly called a seedling tree. Trees from three to ten feet in height are small saplings, and from ten feet in height until they reach a diameter of four inches they are large saplings. Small poles are from four to eight inches in diameter and large poles from eight to twelve inches in diameter. Trees from one to two feet through are standards, and finally, all trees over two feet in diameter are veterans. It is important to remember that all these diameters are measured at the height of a man's chest, about four feet six inches from the ground. In forestry this is, roughly speaking, the general custom.—Gifford Pinchot.

TRANSLATED INTO SPANISH.

The very comprehensive work on the Culture of Citrus Fruits in California, issued by the State Board of Horticulture, 1900, has been translated into the Spanish language and will be published by the Mexican government for the benefit of Mexican orange growers. We learn that the work of translation is now finished and the matter is in the hands of the printers.

BRAWLEY AS A MELON SECTION.

Editor Cultivator: I have frequently noticed in your columns reports of Coachella and Thermal canteloupe crops and, as the president of the Brawley Farming Co., and also of the Canteloupe Growers' Association, I feel it my duty to let readers of the Cultivator know that we can also raise a few canteloupes in this section.

This season the Farming Company raised about seventy-five acres of canteloupes and about one hundred acres were planted by individual growers, of which about forty acres were successful. This left us about one hundred and fifteen acres, off of which we shipped thirty carloads of canteloupes. We sent our first shipment on the 21st of May and the last on the 15th of July. We have reports from Kansas City, Denver, Pittsburg, Chicago and New York that our cars arrived in first class condition and sold for top prices, some cars bringing as high as $800. The quality of the fruit has also been highly commended.

Mr. L. M. Lyon, of New York, was our distributing agent and is enthusiastic over the quality and desired us to plant at least one thousand acres another year. Mr. Lyon will install his vacuum air blower at Brawley to cool the cars, which will reduce our icing charges and at the same time allow us to ship by regular freight instead of expedited freight, which will make a saving of fifty per cent in charges.

This season some of the growers have netted $100 per acre and with conditions and facilities we will have next season, coupled with our experience, we hope to double these proceeds.

The land about Brawley is peculiarly adapted to the growing of vegetables and canteloupes. It is a soft, sandy sediment loam, very rich, combined with abundant supply of water for irrigation, promises a great future for us. Land suitable for raising canteloupes together with water for irrigation, can be rented for $5 to $10 per acre. We have excellent soil, the best of climate and the best of water for growing canteloupes and all other garden products and all that we need is the people to come and farm on a small scale and help to raise that thousand acres of canteloupes.—Peter P. Horley, Brawley.

A large orchard poorly planted and poorly tended will not produce as good results as fewer trees well cultivated.

NOTICE OF MEETING.

A meeting of the members of the Los Angeles County Apple Growers' Association will be held in room A, at the court house in Los Angeles, on Saturday, August 19th, at 10 a. m.

FRED'K MASKEW, Sec'y.

THE "BOSS"
TREE PROTECTOR
Made of Yucca Palm

Is cheap, durable and quickly put on the tree. It prevents Rabbits from destroying your trees. A sure protection against frost, sun-burn, grasshoppers or dry winds. can be easily removed; will last for years.

CITRUS FRUITS

By C. A. Day. Pasadena

ECONOMY IN MAINTAINING THE FERTILITY.

The term fertile is defined as "able to produce abundantly, prolific, productive." "The principal elements of productivity are, a full supply of available plant food, a suitable and continuous supply of moisture, and good physical conditions of the soil. Land may contain large quantities of potential nitrogen, potash and phosphoric acid and other plant food, and yet be unfruitful—infertile."

The application of artificial fertility in the form of stable manure or commercial fertilizers is expensive; it will therefore be economy to first utilize the natural resources of the soil before going to the expense of applying artificial fertilizers, and even where it becomes necessary to increase the fertility of the soil by the application of fertilizers it is still important to utilize to the fullest extent the natural plant food supply of the soil. This may be done by furnishing a suitable and continuous supply of moisture, deep and thorough tillage and a physical condition of the soil favorable for the increase of the quantity of available plant food.

It is my belief that the application of a fertilizer that greatly improves the physical condition of the soil is more beneficial because of its physical effect upon the soil than from the actual elements of plant food contained in the fertilizer. In other words the improved physical condition of the soil due to the effects of the fertilizer may result in changing to available form a larger amount of the natural soil elements than those contained in the applied fertilizer. Stable manure is valuable for improving physical condition of the soil, but as a prominent orchardist remarked in the hearing of the writer, "stable manure is good, but the improved physical conditions do not last and the continued yearly application of either stable manure or commercial fertilizer is expensive."

Another fact that must be considered is that the supply of stable manure in the principal citrus fruit districts is limited. At the present time the general attention of the citrus fruit growers has been turned to the growing of peas and other legumes in the orchard as a green manuring crop. There are several advantages to be gained by this method of increasing the fertility of the orchard soil. It is a well known fact that clover has been used in the eastern States for many years as a means of restoring the fertility of worn out lands and is today one of the great factors in crop rotation for maintaining a high standard of soil productiveness. Government reports say that in Germany the number of pounds per acre of nitrogen added to the soil by legumes is estimated at 200 pounds per acre, and in the United States the average from sixteen States is 122 pounds per acre. When it is remembered that a high grade of nitrate of soda contains but about 15 per cent of nitrogen, while much that is in market contains considerably less, it will be seen that a crop of legumes is equal to from 800 to 1000 pounds of nitrate of soda per acre, which, at the present prices, is equal to from $20 to $25. In the use of the legumes as a green manuring crop for the orchard, the gain in nitrogen is only one of a number of advantages to be gained. The potash, phosphate and other mineral elements of the soil that are assimilated by the root and vine of the pea are by the decay of the plant rendered immediately available for the use of the orange tree.

The roots of the legumes, which penetrate two or three feet into the soil, after decay, open passages down into the subsoil which admit both air and water. The vegetable matter which the green soiling crop gives to the soil, by greatly improving its physical condition, renders available very much larger amount of the natural elements of plant food originally contained in the soil. And further, it is believed that the shading of the ground during the fall and fore part of the winter will retard the maturing of the navel orange crop and enable the tree to hold its crop of oranges with less waste from dropping than when the soil is bare and exposed to the warmth of the sun.

So much has already been said as to amount of seed, time of planting of the crop of peas, the inoculating of the soil with the nitro-culture bacteria, that it seems unnecessary to enter into the details, but it might be well to emphasize two points; first, that on some soils a little fertilizer to start the peas is beneficial; second, government reports say "experiments by Gain and others have shown that peas, beans, and lupins, watered and unwatered, the number of nodules in moist soil exceed those in dry from ten to twenty times." and experiments in this country have demonstrated that the humidity of soil greatly favors nodule formation and of course an increase in the storage of nitrogen. From this it is evident that a lack of rain in the fall and early winter would necessitate liberal irrigation to insure the best results in the increase of nitrogen.

The nitrogen-fixing bacteria belongs to the vegetable kingdom and is of the lower order of plant life, having the power to absorb free nitrogen from the soil air. Air is, therefore, as important to this plant as moisture. A porous soil is favorable for nitrogen storing, and for this reason stable manure is sometimes applied to the soil about the first of August, prior to putting in the crop of peas.

To secure the best results in the storage of nitrogen the bacteria must have a liberal supply of moisture and air in the soil.

OPPORTUNITY FOR THE LEMON GROWER.

In speaking of the opportunity now before the California lemon grower to force the foreign lemon out of the market and capture this country with California grown lemons a local exchange says:

It is unquestionably true that New York consumers would be better satisfied with California lemons than they are with any grown in foreign countries. There would be a reduced element of loss which would be of more importance than anything else. Conditions are so different in New York from what they are elsewhere in the United States that anything which will improve the quality of goods offered here will greatly improve the market. An improved market is essential to secure the best trade and the best profits. With the coming of the California fruit all this would be changed. The market would be better. The fruit would be better and probably two lemons would be sold where only one is wanted now.

The market is unlimited. There are 4,000,000 of people in and about New York City, with fully twice that number within thirty miles. This alone constitutes no mean market. It would be worth while for California growers to secure this market alone. They could ship all the lemons they could produce to New York and rest assured that they would sell at a good price.

Speaking in a general way the New Yorker doesn't care particularly what he pays for an article he wants provided it is up to his standard, but he does object to being fooled with something that doesn't appeal to him, something that he could buy better elsewhere. Further, he has a certain degree of pride in his city and he feels that it ought to have the best of everything. If the best comes to New York he will buy it and pay well. Therefore, if California growers will raise good lemons and send them to New York they can rest assured of a good market nad can be equally certain that they will sell at good price.

More and more each season California lemons are becoming better known. More and more they are coming to be understood as the best possible lemon procurable. More and more customers are being obtained for them. Gradually the foreign product is being pushed out. Where formerly importations ran up to 2,500,000 boxes, they scarcely go over 1,500,000 now. Where formerly there was nothing obtainable excepting foreign fruit the market now has the better California product and is taking to it even more kindly than has been expected.

It would be well if something were done to urge the sale of these domestic produced lemons. It would be well if growers or packers or jobbers would advertiso their excellencies. This was done once by one of the fruit companies, but in late years nothing has been done in this market to add to the knowledge already possessed. It was shown at that time by analysis that the California contains more of the distinctive lemon ingredients and elements than the foreign lemon, but the supply was so small at that time that few could obtain them, consequently that excellent bit of advertising didn't amount to much. It was, however, an indication of what should have been done ever since. It ought to be the regular thing to undertake work of this sort and show how much better in every way the California lemon is.

FLORICULTURE AND GARDENING

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

REVIVAL IN CACTI.

Every decade or two we have what critics are pleased to term a "cactus craze." Ten years have now passed since the last local revival in this most interesting family and there are signs of a slow return of cacti to public favor. We still have, in many parts, fine collections which have been well kept, but with interest at low ebb some of these may be purchased at most sacrificial prices. With the return of cacti to general favor these fine private collections will rapidly increase in value. If you wish to be "in" on the next high tide of the cactus craze, begin collecting at once.

No other natural order furnishes us, at one and the same time, with so many curious forms and lovely flowers as does Cactaceae. The plants range in size from a little larger than a pea to more than sixty feet in height, with so many curious forms as to completely baffle description of many of them. Of course the size of the flowers have no such range, but several are more than a foot long and of the same diameter across the mouth, when in full bloom. No family of plants can surpass the exquisite shades of color to be found in cacti, ranging from white to crimson, all with a beautiful satiny finish. Collect cacti.

THE CALIFORNIA FAN PALM.
(Washington filifera.)

Beginning a little more than one hundred miles eastward from Los Angeles, along the line of the Southern Pacific to Yuma, and extending to the head of the Gulf of California, lies what is known as the Colorado desert, or such part of it as lies within the State of California. Not long ago, a few centuries at most, this was a vast inland sea. Whether it was upon its present level or has been raised in places, no one may say, but parts or it are now nearly four hundred feet below sea level and the water marks on the rocks, where the lapping of the waves have worn them away, are as distinct as though the waters receded but yesterday and apparently are on a perfectly level line. In the canons which extends like giant arms from the desert body, stands all that exists of the only palm native to the Pacific Coast States, Washingtonia filifera, or as it is commonly known, the California Fan palm. All told, they now number but a few hundreds, though it is certain that when they were fanned by ocean breezes they were almost innumerable, perhaps the beach was thickly planted with them, as is the case in many places with the cocoanut palm. One circumstance that bends the curious investigator to this opinion is finding them at present only where the roots may reach water or very damp soil. A majority of persons, speaking of this palm, will be heard to exclaim, "Oh, they will grow anywhere; they are natives of the desert;" not knowing that when one "on the desert" blows over, the hole beneath immediately fills with a brackish brine, too salty by far for drinking purposes; yet such is the case with all those growing along the edge of and upon the desert floor. In the canons they all stand in or near pools or running streams, except perhaps for a short period in midsummer when the canons are dry. Here, where they are comparatively free from the desert storms, their bare black trunks may be found from forty to eighty feet in height. Unlike those in cultivation, no part of the trunk is covered with the hanging dead leaves, occasional fires keeping them burned off clean as far up as the green leaves.

Our species is also found in Arizona just across the Colorado river, but their numbers are few. Mexico (Sonora and Lower California) gives us two other closely allied species, W. Sonorae and W. robusta, the latter being by far the most handsome. Though all Washingtonias are doubtless diminishing in their native haunts, so far as numbers are concerned, this need give no cause for alarm, by reason of the many thousands found in cultivation which alone produce enough seeds to supply the world's demands.

A Good Cactus Collection.

THE OPIUM POPPY.

The best ground for the culture of the poppy (Papaver comniferum), according to information received from Smyrna, is a light soil on a hillside having a rocky subsoil. This produces the light-colored opium, which is most esteemed. A low saudy soil of a dark color will produce a dark quality of opium, which is inferior to the former. To produce opium of the finest quality it is essential that the ground should be rich and dry.

After the first rains in September the ground is plowed several times at intervals, and well manured. Sowing usually commences in October. The seeds are mixed with two parts of earth, and sown broadcast. Many farmers consider it advantageous to draw a rake over the surface after sowing, in order to cover the seeds. Sowing at this season produces a better crop than at a later period, as the plant becomes stronger, and is not so likely to be injured by the cold. It has, moreover, this advantage, that, should the crop be destroyed, seeds can be sown again during the months of December or January.

As soon as the plants attain a growth of two inches they are thinned out, and a space of several inches left between them. The ground is then hoed, in order to lighten the soil as much as possible, and give air to the roots. This process is sometimes repeated while the plant is yet young.

The business of collecting the opium commences after the flowering of the poppy, which usually takes place about the 1st of May. Should rainy weather prevail, however, the capsules will not easily ripen, and the collecting must be deferred till the following month. The harvest continues through June, July, and to the middle of August. The change of the color of the capsule from green to gray indicates that it is ripe for the process required. This generally occurs from five to ten days after the withering of the flower, according to the state of the atmosphere. A small incision is then made on the side of the capsule as a test, and from this a milky substance is shortly seen to exude. If this falls to the ground the plant is allowed more time to mature; but if it trickles slowly down the side and adheres, there is evidence of full maturity. The operation for obtaining the opium now really begins. Curved incisions are made with a peculiar knife all around the capsule through the epidermis, or outer skin, and after a few hours the opium which has exuded on the surface is collected. One company of men are employed in making incisions upon such plants are they judge to be in a fit condition for the operation, and these workmen are followed, a few hours later, by others who collect the soft juice by scraping it off, and placing it on a tin plate held in the hand. When a sufficient quantity has been collected, it is transferred to a large leaf, in which it is enveloped. This leaf belongs to a plant closely resembling our domestic lettuce, and grows wild throughout the interior. Only the first quality is treated in this way. The inferior article is removed from the plate into a shallow wooden tub, in which it is left a few days to dry, and then rolled into balls of various sizes, and enveloped in leaves in the same manner as that of the first quality. These balls, varying in weight from one to three pounds, are placed in high narrow baskets, each being lined with fine linen made into a bag. Between the layers, and even between the balls, a quantity of an extremely fine husk of a certain grass, which everywhere abounds, is strewed to prevent the whole from becoming one mass. Each layer is firmly pressed down, and when the bag lining the basket is full, it is strongly tied, and sealed with the seal of the owner. In this state it is brought on mules or camels to the Smyrna market for sale.

The purchase is concluded previous to any examination of the article, the understanding always being that it must be of the first quality. The baskets are conveyed to the warehouse of the purchaser and opened only by the public examiners, who examine each piece, cutting open any that appear doubtful, and setting the second quality aside to be returned to the seller. These examiners, by long practice, become very expert in their business, and can tell at a glance, not only the quality, but even the district in which a certain parcel has been collected.

The work of collecting opium is performed both by men and women. The average cost of producing a chequi of opium of one and two-third pounds, not including cost of plowing or land rent, may be estimated at forty piasters, or about $1.60.

It may be remarked that the poppy is an exceedingly tender plant, the growth of which is attended with many dangers before arriving at maturity. A slight frost, continued rains, or great heat may ruin the crop of a whole district in a very short time. To be brief, the requisites for the proper development of the poppy are these: A rich, dry soil, proper culture, slight rains during the early part of its growth, and moderate heat at the time of flowering, to bring the capsules to maturity.

SAVING VEGETABLE SEED.

To save or clean pulpy seeds, such as cucumber, tomatoes, etc., I scrape out the inside pulp into a dish, set it in a moderately warm place for 48 hours, or till it sours, then beat it with a stick as I would an egg. Then fill the dish with water, drain off and repeat until the seed is bright and clean. Spread to dry, then pack up and label with date.—O. J. Farmer.

General Agricultural Notes

AGRICULTURAL KNOWLEDGE

There is a theoretical and practical knowledge of agriculture, says Drovers Journal. The former is obtained from books and the latter from personal cultivation of the soil. If, without experience, one undertakes to operate a farm he will soon discover that there are a multitude of facts to learn before he can achieve the best results. Conducting a farm successfully is not only a business, but a science that has to be mastered as much as medicine or mechanics. The farmer is engaged in a business that needs comprehensive knowledge of the laws of plant and animal life, as well as the composition of soils, if the greatest results would be attained. Farming involves so many uncertainties that skill and experienced judgment are in constant demand. When the city farmer engages in agriculture late in life without experience, he will soon learn that his operations are a mass of mistakes, and he will be compelled to learn from those whose knowledge and experience have blazed the pathway to success. The new beginner will find experience forthcoming and money outgoing until he has learned the facts necessary to follow agriculture successfully.

One may obtain a theoretical knowledge of banking and telegraphy from books, but could not send a dispatch or conduct a bank without apprentice experience. One must have a love and aptitude for farming if he would succeed. There are so many facts to learn in any branch of agriculture that time is necessary to acquire experience. It is not the ability to raise one bumper crop, but to so manage agricultural land that good crops can be produced every season. This requires a knowledge of the composition of soils and the most practical and economical method of maintaining and increasing land fertility. If the experienced achieve only average success what can the novice expect in agricultural operations?

A successful farmer must know the fundamental rudiments of animal and plant life. The more extended his knowledge in these laws the greater the prospect of success. He need not be a college graduate, but he must have mastered the laws governing plant and animal life and the particular adaptation of plants to the soil which he cultivates. This knowledge, combined with the ability to do this work to the best advantage, will command success. A little knowledge is a dangerous attribute, especially when it does not take in the whole problem of any branch of agriculture. What is needed on the farms today are competent and experienced men who have mastered the principles of agriculture at either experiment stations or practical field and livestock operations.

NATIONAL IRRIGATION CONGRESS

From the official call of the executive committee of the National Irrigation Association, of which Gov. Geo. C. Pardee is president, and C. B. Booth, of Los Angeles, is chairman, we note the following:

The Thirteenth National Irrigation Congress is called to meet in Portland, Oregon, August 21st to 24th, inclusive, 1905, convening in the Auditorium, Lewis and Clark Exposition grounds.

All who are interested in developing the great natural resources of the country, extending the habitable area, and increasing the products of the land, insuring greater stability and more prosperous conditions, making occupation upon the land more attractive, the extension of the internal trade and commerce, and the dissemination of a wider knowledge of the great economic movement which has for its ultimate object the upbuilding of an empire within the borders of a great nation, are invited to attend the Congress.

The work of the Congress has been so greatly enlarged through the increased interest in matters pertaining to irrigation, that the executive committee has decided to systematize the work of the next Congress according to Articles 3 and 5 of our constitution; consequently the work of the 13th Congress has been divided into five sections.

Each section will be conducted by a chairman, who will be recognized as an eminent authority in his line, which insures a thorough exposition of the respective subjects through the presentation of papers, addresses and discussion by the most eminent men interested in forestry, irrigation, climatology and their correlated subjects.

In the various sections, information will be dispensed regarding the increasing of production by irrigation in the humid as well as in the arid sections; forestry problems in New England, and along the Appalachian Chain, as well as along the Rocky and Sierra Mountains; engineering applied to protect from the devastation by floods; drainage of the submerged areas; directing and conducting the water to its most beneficial use; climatology with special reference to the srevice of the Weather Bureau throughout the United States; and colonization of new areas developed through irrigation.

THE VERDICT IN THE MITCHELL CASE.

Presumably the age of John H. Mitchell, senator of the United States, is responsible for the generous recommendation of mercy which accompanied the jury's verdict of guilty in his case. Certainly neither his public position nor his dramatic protestation of innocence, coupled with expressions of virtuous indignation against alleged political enemies maliciously seeking his undoing, at the time the indictment was returned against him, warranted the suggestion.

Senator Mitchell is convicted of complicity in the startling land frauds which, as readers are aware, had for their object the alienation of millions of acres of the public domain by conspiring thieves and boodlers. The technical charge against Mitchell was that of "practicing before the departments of the United States government for compensation while occupying the office of United States senator." What he has been guilty of, according to the testimony of his own partner, who was a very reluctant witness, is the expediting, for pay, of land office cases known to him to be fraudulent and corrupt in origin and character.

The defense, in spite of previous assurances of the defendant's resolute desire to secure prompt vindication and prove his innocence, was wholly technical. Neither the demurrer to the indictment nor the argument and objections of his attorneys at the trial had any relation to the merits of the case. The jury, if we may judge by the reports of the proceedings and the evidence, simply could not return any other verdict.

The resulting spectacle—another federal senator in the pillory, convicted of crime inspired by greed—is not a pleasant one, but it is very much pleasanter than the knowledge that "respectable" rascals evade justice and escape punishment. Let the wholesome work go on. The Secretary of the Interior said in his last report: "The leading spirits in the fraudulent transactions" in question "are mostly men who have occupied positions of influence and high standing, both socially and politically, and many of them are men of large wealth." It has required and will require much courage and determination to overcome the obstacles placed by these conspirators and criminals in the way of justice. Such courage and fearlessness the people expect of the departments concerned. —Chicago Record Herald.

Milk is just about all water, but the only honest way to get it is through the cow. The only way cows have of getting water is the way you and I furnish them. If we fail of doing our part, the cows certainly will draw the lines on us when it comes to milking time.

Don't think that because fruit is off the tree that it needs no more water or cultivation this year.

Spade and fit ground for fall bulbs.

Wash the shoulders of work horses.

Cereal Crops of California—There is much disappointment among wheat growers at the results of this year's crop, not only in amount, but in quality. Up to sixty days ago it was generally believed the wheat crop would be normal. Early conditions of weather and moisture presaged a bountiful yield, but when examination was made it was found that early estimates were entirely too high and instead of a yield of 650,000 tons, 400,000 tons would be nearer the right figure, and even that amount is questioned by very conservative operators. The San Francisco Chronicle says:

"Samples of new wheat recently received in this city show the grain to be badly shriveled and of necessarily light weight, some of it averaging only forty pounds to the bushel. Strictly choice wheat will be decidedly scarce, and millers are even now placing orders in Oregon and Washington for their requisite supplies."

Those growers in Northeru California who have good wheat, that is wheat of good quality, will realize a handsome figure for it, and those whose wheat is inferior in quality will of necessity get a fair price, although they will not realize anything like what they expected from their harvest. They will probably get their expenses back, but no profit will be made.

Barley shows up much better than wheat, and the San Francisco Chronicle believes the yield of the State will be upwards of 650,000 tons. This is a satisfactory crop, and that grown in the coast counties will grade well, in both quality and weight. Oats are not very extensively grown in this State, but judging by the samples already received in this city, the quality is good and growers will doubtless receive remunerative returns.

* * *

About the Apple Crop.—The world's favorite fruit, the apple, is going to be scarce this winter and it now looks as if we shall have to pay as dearly for apples as the easterner does for lemons just before the fourth of July.

The Chicago Packer recently sent out a hundred or more telegrams into the apple districts of the United States and the information returned is summed up in the statement that "the crop will be 40 per cent short of last season's crop, if not more." Considering the fact that the crop was light, in most districts, last year, this information is not pleasing. When we consider that apples constitute our standard for fruit, as much as bread does our meals, the cutting down of 40 or 50 per cent of the crop is not a desirable fact to contemplate. We might possibly work through on this side, if European countries would let us alone, but already the demand is coming in for apples in such quantities as to lead to the belief that there are none to speak of across the Atlantic and that all the winter apples produced in America which can be spared will find a market in foreign countries. Prices undoubtedly will be high this fall and we shall be thankful to get even a moderately good apple and pay a fair price for it.

* * *

An International Bureau of Agriculture.—Once more California has come to the fore with a scheme to better existing conditions for the farmer, if we may rely upon information received from Washington. This time it is Mr. David Lubin, of Sacramento, who is credited with the conception of the plan proposed by King Victor Emanuel of Italy, which is to organize an International Bureau of Agriculture. Mr. Lubin explained to the king his project and the latter at once approved it. The king has organized an international chamber with headquarters at Rome, and suggests that other countries do likewise. The promoters believe that by this means "agriculture may be so centralized as to be able to face capital and labor, which are already organized and centralized in opposition to it, in the economic struggle." Government officials in the United States have not learned enough about the details to express themselves except in a general way. Secretary Wilson of the Department of Agriculture said that he was heartily in favor of measures that would be of advantage to the farmers the world over. He believes that this may be accomplished by an accurate exchange of information as to the principal crops of the world.

* * *

Good Suggestion.—"In displaying the advantages of California to Eastern home-seekers," says the San Francisco Chronicle, "the place of honor should be given to the dairy rather than to the orchard. The number of Eastern farmers who understaud fruit growing is limited, but every one among them understands the dairy and its profits. The effect of alfalfa upon the milk supply should be made much of, as well as the peculiar advantages of the climate. But it must be always remembered that practice is better than precept, and the California farmer who neglects the dairy is not only depriving himself of a considerable revenue, but he is detracting from the showing of the State as a whole. California ought not to import her dairy products, and the dwindling statistics of these transactions will mark the progress of the State toward agricultural sanity."

* * *

Diversified Farming.—With the advent of abundance of water into Southern California, will come a more general character of farming. In the north of the State this is true today. The farmer there does not depend wholly on one, or two kinds of crops; he mixes his grain growing with cattle and hog raising and when he is forehanded enough he adds a dairy. Down south of the Tehachapi our farmers have of necessity been circumscribed in their endeavors. They have felt that it is not safe for them to branch out too extensively into diversified farming lest they might be confronted by lack of water some time. Now, however, that danger is soon to be averted and water to do anything they care to undertake will be at their disposal. They can have both alternative and supplementary sources of income. They can raise fruit, vegetables for home consumption and the market, and to these add the dairy which, if properly conducted, is always a winner. Along the line of what appeared in this paper a week ago, concerning the possibilities of California, when the Owens river pours its waters into the southern part of the State, the Breeders' Gazette suggests that "there is abundant testimony that the farmer who can raise good cattle on home-grown feeds and sell them at an average of $100 is certain to make money. There is, of course, the personal equation, but even when allowance for this has been made the man who owns his land, has good pastures, with barn and an alfalfa and clover meadow, can hardly make a failure of it."

The Gazette recommends the purchase of a few good bred heifers, of some favorite variety. The first lot of calves will go far to pay for the purchase price. Whenever the herd reaches the size that is rendered desirable by the capacity of the farm the surplus can be sold. Prices will not, of course, be high, but they will certainly be remunerative for all desirable stock. A fortune is by no means necessary for a start. A small beginning can be made without a great outlay or a large farm, and the business can be extended as opportunity may offer. For the farmer who wants to make money and to put his land to the best and most remunerative use on a small capital there can be nothing safer or better than intelligent stock raising.

Under existing conditions this is not practicable in Southern California, but it is in Northern and Central California. However, these conditions will all be changed in a few years, and it will be possible to raise stock and operate dairies when the Owens river project is developed, as easily in Southern California as in any other section of the State.

* * *

Tell Your Friends.—The Cultivator is getting to be so valuable that every farmer in California will have to take it to keep abreast of the times. We not only say it is the best paper of its kind on the coast, but we believe it to be. It is prepared with the utmost care to make it of value to readers, the best talent in the State is employed in its several departments, and just as fast as support comes to it to warrant it is enlarged in size and otherwise improved. That it is carefully read there can be no question, for scarcely a week passes that letters are not received commending its position on public questions, or asking for information on subjects pertaining to agriculture, plant or animal life. The paper has more than 10,000 subscribers, it is read every week by 20,000 or more people. It ought to have twice the number of subscribers and be read by 40,000 people each week instead of 20,000, as at present. All that is needed to double its circulation is to acquaint new comers to the State with its character and worth. We desire to suggest to the old time friends of the Cultivator that you make a point of telling your neighbors of the real worth of the paper; for by so doing you will help to increase its circulation, make improvements in the paper come sooner and assist the publishers in making the greatest general farm paper on the Pacific coast.

Valuable as we believe the paper is, our friends may help us to make it even more valuable. If you have a better way of cultivating corn or potatoes or any other farm crop than your neighbors, write your experiences and let us publish them for the general good. If your hens lay more eggs, or your chickens make a finer growth, keep in better health and prove more profitable than theirs, tell us for publication how you manage to get such good results. Tell us how you manage your orchard to produce the best fruit; tell us how you feed and care for your cows to make them give so much milk and butter. Tell us about the various and sundry farm economics that you have discovered, whether in the house, the barn or the field, and let us publish your methods for the benefit of others. Every farmer knows something that would benefit his brother farmers, and he should be willing to tell it. If all the readers of the Cultivator will do this, we can make it the most valuable and interesting weekly magazine in the country. We can not estimate the value of exchange of thought and methods of work to accomplish results. Knowledge is power and the more we can have of it the greater will be our success.

* * *

Doctor Moore Discredited.—The National Stockman and Farmer, in its issue of August 3, presents an editorial on the subject of nitro-culture, which is interesting and valuable in that it exploits the connection of Dr. Moore, late bacteriologist in the Bureau of Plant Industry, with a firm which is preparing the compound as a commercial fertilizer, and selling it to the public under the impression that it has the endorsement of the Department of Agriculture.

Dr. Moore, it will be remembered, has resigned his official position with the department, and the fact that the compound his firm and others are offering to the public is not endorsed by the Department of Agriculture, raises the question as to whether it is best for farmers to purchase this fertilizer until its merits have been proven. In this editorial the National Stockman and Farmer says:

"Acting Secretary Hays authorizes us to make the following statement:

"Assistant Secretary Hays is making an investigation into the matter of the value of nitro-cultures, and permits us to say that people would do well to await the results of this investigation before depending too much on nitro-cultures from commercial firms."

The Cultivator, having made mention of this fertilizer in several numbers, desires to publish at this time the advice offered in connection with its further use.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Prune drying around Healdsburg has commenced.

Redlands has shipped 3668 cars of citrus fruits this season.

The peach crop around San Jacinto promises to be a big one and of good quality.

The grape crop in the hill sections of the Pajaro valley is reported very promising.

Many table grapes are being shipped out of Dinuba in car lots to the San Francisco market.

The fruit crop at Auburn is moving rapidly. Pears are coming in but the crop will be light this year.

Wm. McLaughlin has sold his crop of Valencia oranges from five acres at Anaheim for $3200 net on the trees.

Word comes from Marysville that pears are bringing as high as $65 a ton. This price will net orchardists a profit in spite of poor crop.

Leonard Coates, the old Napa nurseryman, has removed from Fresno to San Jose and will go into the nursery business on a large scale.

The work of harvesting the crop of Gravenstein apples about Watsonville will be completed by the 15th. The crop is the best in years.

The apple crop of the Pajaro valley is estimated at three thousand carloads for the season, which will be the largest in its history. Codling moth are not nearly so much in evidence as in former years.

The co-operative winery at Woodbridge, San Joaquin county, is nearly completed, and will commence on its fall work next week. The stockholders represent 1000 acres of wine grapes, every acre counting one share.

From six acres of the Giblin orchard near Marysville, seventy-four and a half tons of peaches have been picked this year. At the prevailing prices, this will be worth in the neighborhood of $3750, or an average of $625 an acre.

The State Floral Society will give a fall exhibition in the Ferry building, San Francisco, the latter part of October. The Southern California Horticultural Association will hold its floral exhibition at Los Angeles November 2nd, 3rd and 4th.

The Highland Messenger says: "The fruit exchange has received $80,000 on proceeds for eighty consecutive cars of lemons, shipped since July 1st, an average of $1000 per car. The figures are not less than astounding."

At a recent meeting of the members of the A. C. G. Exchange at Glendora it was decided that the Charter Oak association might again affiliate. The present packing house is to be enlarged. The association will discontinue fumigating and sell its outfit.

A dispatch from Lodi states the price of Tokay grapes has advanced from $150 per acre for the crop to $180 per acre, the purchasing company to pick the grapes. The grape crop in northern San Joaquin is reported heaviest in years, over one thousand acres of new vines coming into bearing this season.

Our field man in Santa Clara county writes that canneries are busy with plums, apricots, pears and peaches. Crop of apricots is heavy in the valley, peaches and prunes are light, but along the foothills there is a good crop of both and the quality extra fine. Growers are generally holding for better prices.

The Lindsay Fruit association has passed the following resolution: "Resolved, That whereas the selling of cull oranges to peddlers in Tulare county is doing the orange industry an immense amount of damage, it is the sense of this association that all culls should be destroyed by the packers and growers of this county, and that the co-operation of all associations and growers be invited to obtain the complete destruction of all such fruit."

The California Citrus Union has paid at Colton the following returns to its growers for Mediterranean Sweets: First pool, fancy, $1.78 per box net to growers, or $2.63 per 100 pounds; choice, $1.48 per box net to growers, or $2.18 per 100 pounds. This is at a rate for all Sweets delivered at the packing house on this pool, including culls, of $2.228 per 100 pounds. Second and last pool, fancy, $1.86 per box net, or $2.7353 per 100 pounds; choice, $1.60 per box net, or $2.35 per 100 pounds; standards, $1.40 per box. or $2.05 per 100 pounds.

The Swiss-Italian colony at Asti, where is located the largest wine tank, is now in shape to handle six or seven thousand tons of grapes. The season will commence early in September, and one and one-half to two million gallons is the annual output. We understand the colony, in connection with the California Wine Association, is to put up a large office and bottling works in New York, where California wines under California labels will be extensively handled and advertised. California wine is as good as the French if the people would only think so.

AGRICULTURE.

The new crop of hay is arriving at San Francisco at the rate of 5600 tons per week.

Harvesting has commenced on the San Joaquin ranch, Orange county, of the 6000 acres of beans. A heavy yield is anticipated.

There will be a meeting of the hop growers at Ukiah, August 12th, for the purpose of fixing the price of picking the coming hop crop.

Already there have been threshed about two thousand cars of grain in Riverside county and about thirty-five machines are still working.

The second fire of the season visited the big Dunphy ranch in the southern part of Monterey county last week, destroying a large amount of grain.

One of the largest chili pepper crops will be grown this year around Anaheim. The growers hope for the price to range from eight to ten cents per pound, which will net them from $100 to $200 per acre.

O. W. Lewis, of Fresno, who recently purchased a section of land two and a half miles west of Corcoran, is having four wells put in the tract and as soon as the planting season arrives will set the entire section out to asparagus.

One million dollars has been distributed among the citrus fruit growers belonging to the associations that comprise the Ontario-Cucamonga Fruit Exchange this season, the majority of the fruit of this exchange having been shipped from Uplands.

The Exeter Sun says that the association at that place has shipped some 6000 boxes of cantaloupes. Last week the growers received $2.25 f. o. b., Exeter, which leaves a big profit for the grower. In addition to cantaloupes, a large number of watermelons in carlots have been shipped.

The Fullerton Vegetable Union at its annual meeting last week elected the following directors: T. B. Steward, W. Parrott, Geo. Porter, Henry Meiser and August Miller. J. A. Vail was reelected manager. The sweet potato growers will go into the organization again this season. Last year this organization marketed 8500 sacks of sweet potatoes, which sold for over $10,000. It is estimated the crop this year will be fully as large and will come in the market commencing August 15th.

LIVE STOCK.

Two special trains of beef cattle were shipped from Willits to Santa Rosa last week.

The recent rains in the San Simon valley, Arizona, have put the ranges in fine condition.

Sonoma dairymen are talking of organizing a stock company to build and operate a creamery.

The Sherer 80-acre ranch near Compton, with 77 head of cows, has been leased by John J. Pace, of Ventura.

The Pacific Coast Trotting Horse Breeding Association will hold its annual meet at Santa Rosa commencing August 16th.

The Maple Grove creamery plant at San Luis Obispo has purchased the machinery of the creamery on the Santa Manuela ranch.

The Fairchild-Wilton-Gilmore Co., at Victorville, have recently put in an irrigating system on their three hundred and twenty acre ranch on which they propose to raise stock.

The Chino Land and Water Co. has contracts for all of the beet pulp of the big sugar factory there and is now negotiating for some three thousand head of northern cattle which they will fatten there for the market.

The creameries at San Jose have each been trying to secure control of the cream output in the vicinity of Gilroy. As a result, bids were offered at two cents per pound above prevailing market prices which were accepted by the dairymen.

MISCELLANEOUS.

Eleven counties will make exhibits at the coming State fair.

The Humboldt county fair will be held at Eureka, September 11th to 16th

A civic improvement club has been formed at San Gabriel with 120 members.

An average of two to three cars of tan bark are shipped from Healdsburg daily.

Jacob Stoner has purchased the Thieme packing house at Corona; consideration, $6200.

Ventura county bee men are hauling their bees to the valley country that they can feed on bean blossoms.

The Ontario Record issued a fine 68-page magazine number last week, giving a thorough writeup of Ontario, the model colony.

Returns from county assessors from fifty of the fifty-seven counties of California show an increase in assessment of $84,029.258.

The Parker Brothers are to sink a well 2500 feet deep on their ranch in Graham county, Arizona, with the anticipation of striking artesian water or oil.

The Kings county supervisors report a valuable discovery in making new roads. After the roads are oiled, they cover with straw, saving a great waste of oil.

The Southern Pacific announces that it will soon commence the construction of a branch to Oregon line from Drain to Coos Bay, a distance of eighty-one miles.

The Southern Pacific road announces that they will spend $10,000,000 in railroad building in the States of Washington, Oregon and Idaho within the next year.

A fire near Bloomington last week destroyed the apiary of Mrs. W. H. Smith. Sixteen stands of bees, a honey house and considerable canned honey were burned.

A new glass manufactory is to be established at Monterey. The plant will be of thirty-six blow capacity, and will give employment to about three hundred men.

The Santa Fe will construct a branch line from near Reedley to the new winery of the California Wine association. This winery is one of the largest in the State and will handle the product of many thousands of acres in that section.

H. E. Huntington has been granted a fifty year lease for space in the outer harbor at San Pedro on the agreement that he is to build large wharves. Mr. Huntington intends using the harbor for the use of the Oriental trans-Pacific trade.

The Butte County Canal Co. is trying to secure contracts for irrigation of ten thousand acres of land in Sutter county next year, when the work of extending the canal will commence. At present the canal is built to the Sutter county line on the north and supplying water to thousands of acres of land in Butte county.

Our correspondent in the north writes: This month is the open hunting season in Sonoma county. In Mendocino county it lasts until September 15th. So the deer are having a strenuous time about now. The Russian river banks and the mountains are alive with campers at this season, mostly from other sections, while the residents here are away camping in other districts. Anything for a change. Hop pickers too, are on the move and will soon be in demand to gather the coming crop.

C. H. SESSIONS, ASSOCIATE EDITOR

WEANING THE PIGS.

Thirfty pigs are generally ready for weaning at seven weeks old, and in order that their growth may not be materially checked at this time it is well to teach them to eat a little before they are ready to be weaned. This can best be done by pouring a little milk, sweetened, if necessary, into a shallow trough out of the sow's reach, and if one of the pigs can be induced to drink the others will follow. You must provide dry pens, plenty of shelter for bad weather, clean troughs and feeding floors. Subject the porcine friend to damp sleeping quarters in fall and winter and you will knock out his constitution. Rheumatism and other troubles will result. Filthy feeding troughs mean filthy bowels and worms, with a weakened body that cannot throw off the poisons of plague or cholera. Dusty feeding grounds mean coughing and sometimes aggravates tuberculosis. Provide floors where needed and have hearty, healthy hogs. Put brains into the work among hogs. Drain the hog yard and give them alfalfa to roam in. Make the roof of the hog house one series of doors that can be thrown back, letting in the sun to purify the interior. Use air-slacked lime to keep things clean. Just because the hog drinks out of a wallow do not think he is naturally filthy. Put some money into a few real necessities for his proper care. It pays. Raise hogs by making a business of it.—Farm Magazine.

WHITE SPECKS IN BUTTER.

In reply to query Hoards has the following:

The cause of white specks in butter is usually overripe cream. When cream sours too far before churning, the curd in the cream is hardened by the continued souring and contracted into small white specks which may be retained in the butter if not removed by washing. As a rule, butter of this sort is more commonly made in farm dairies than in creameries, because at the farm dairy, cream is collected for several days and the first lot of cream is likely to be very sour before the mixture of several days' cream is churned. This separates the curd and although it is mixed quickly and thoroughly through the cream during churning, the harder specks are apt to be left in the granular butter and not washed out with the buttermilk.

Butter made from cream containing this kind of curd can be freed from these white specks by washing the granular butter in the following way: When the butter breaks and the granules are about the size of wheat grains, draw off the buttermilk, then fill the churn about half full with cold water, revolve it a few times and let the churn stand until the granular butter rises to the surface of the water; the curd being heavier than the butter will sink to the botton and may be drawn off through the draining plug at the bottom of the churn. By repeating the washing of the granular butter in this way, one can separate the hard specks of curd very readily and thus prevent their appearance in the finished butter.

MILK FEVER TREATMENT.

The Cultivator has given many times the air injection treatment for milk fever, but it is yet unappreciated by many. A speaker at a recent eastern dairy meeting referred to its importance as follows: "Every farmer ought to have a bicycle pump fixed with the tubing, and on the end of that he can put a small milking tube or goose quill. Put your bicycle pump in boiling water and let it remain there five minutes, so as to sterilize it in order that no bacteria may be carried into the udder. With this pump you inflate one quarter of the udder until it is fairly well distended, then the next quarter, and repeat this until all four quarters are fairly well distended; then give the udder a thorough massage, rubbing it well. I forgot to mention that all the milk from the udder should be removed before any air is forced into it. Rub the udder thoroughly and that is all there is to it. You do not need to do anything else. If you can remove the excreta, well and good. If the cow does not get up in an hour, repeat the injection. I have never known of a dairy farmer who has tried that treatment without having great success. It is a very simple treatment."

There are more up-to-date appliances now advertised in the Cultivator which may be used. These should be purchased and kept on hand for emergency. Dairymen who wish to be on the safe side should take no risks, as the remedies for milk fever that have heretofore been used are not to be compared in effectiveness with the sterilized air treatment.

A. J. C. C. AND THE BUTTER FAT TEST.

Owing to much contention as to the best method of testing the capacity of a cow to produce butter and the position taken by the American Jersey Cattle Club, which it has been claimed is often misunderstood by the press, we give the following by R. M. Gow:

Some of the agricultural papers of the country have been industriously spreading strange news in regard to the attitude of the American Jersey Cattle Club on the question of testing milk by the Babcock process. We have been told that fossilism is in control of this association; that it sticks to the foolish churn test idea; that for unreasonable obstinacy it takes the plum; that it displays painful ignorance of the progress of dairy science, etc., etc.

As the "painful ignorance" is altogether on the part of the papers which persist in this line of statement, the dairy public will probably welcome correct information on this subject. The A. J. C. C., composed, as it is, of

TUBULARS WRING GOLD FROM MILK

Tubular butter brings 25 to 35 cents. Cream is worth only one cent for stock food. Yet many farmers have no separator—only half skim their milk by setting—lose 24 cents on cream fed to stock—and wonder why dairying don't pay. **Tubulars stop this loss. Tubulars get the last drop of cream out of the milk**—make big profits. Tubulars are the only modern separators. Notice the low can and enclosed gears. Write for catalog S-260

MEALFALFA

Reg. U. S. Patent Office

AS A HORSE FOOD

Horses in cities, as a rule, are fed upon grain and grain hay. These feeds are far too heating and the result is that the horses finally burn out and break down. ***Mealfalfa,*** being a green feed, rich in protein, is an excellent remedy, as it cools the blood and keeps the horses in fine condition by regulating digestive disturbances. It furnishes material to make bone and muscle, builds the horse up, makes him strong and gives his coat a fine glossy appearance. It is the best food for all draft, livery or driving horses. If you feed oats straight, use one of ***Mealfalfa*** with every four of oats. If you use barley and oats mixed, use two of barley, two of oats and one of ***Mealfalfa.*** If you use crushed barley, mix two parts crushed barley to one of ***Mealfalfa.*** Mix it dry in a bin. In this way your horse gets the best ration possible and in the most digestible manner. It will prevent your horse from breaking down.

In case your horse ever becomes sick, feed him ***Mealfalfa*** as a wet mash and you will get favorable results quickly.

practical dairymen, progressive breeders, successful business men, prominent statesmen, and members of the various learned professions, is the last body in the world likely to be behind the age on any practical question affecting its interests. Among its large membership there are doubtless differences of opinion as to the relative value of the various methods of testing dairy cows, but the consensus of opinion in the club is embodied in its laws and rules, and those rules provide for the acceptance of tests made by all approved methods, both privately and officially applied. The club is not composed of either fat test faddists or churn test faddists, so neither method of testing has been rejected, but each is given its due place. Some outsiders would have the club abolish the churn test entirely as obsolete and inaccurate, but there is no good reason why this should be done. The confirmed butter tests made under the rules of the club are made by the fat test in the hands of representatives of the agricultural colleges, supplemented by the churn in the hands of the owner of the cow or his agent, the two methods being thus independently applied in each case, and these tests have proved the accuracy of both the Babcock test and the churn test, the average difference between the two tests being but 5⅝ oz. butter per cow per week in favor of the fat test, and this difference is fully accounted for by the necessary loss of some of the fat in the skim milk and buttermilk. So there seems to be no good reason whatever why the club should reject churn tests on the score of such tests being inaccurate, to say nothing of the desirability of acquiring evidence of the churnability of the milk and the quality of the butter; for in the production of butter it is the fat that can be recovered in butter that counts, not what may be found chemically as present in the milk.

But at the same time no stigma whatever is cast by the club upon the fat test, either expressed or implied. A churn test or a fat test, if made in accordance with the club rules, and if the required standard is reached, equally entitles a cow to entry in the club's Register of Merit. Both methods of testing are put upon an exact equality, and, as has been said in the case of "confirmed" tests, both methods are employed, each to verify the other. In the case of the cow demonstration at St. Louis, where churning was impracticable, the club freely accepted the Babcock fat test, under which the Jersey herd competed, evidence enough, if evidence were needed, that the club has no objection to or prejudice against the fat test; for, let it be fat test or churn test, the Jersey cow does not fail to come to the front.

DON'T BE FAMILIAR.

Regarding the temptation of being familiar and making a pet of the young bull, we note the following in an exchange:

Farmers sometimes allow their boys to become entirely too familiar with the bull calf by encouraging him to become playful. Boys, do not do this. Preserve your dignity when you are about the bull calf. Treat him kindly, but give him to understand always that you are his master. Never let him know how strong he is, and never trust him. You may have confidence in any other live stock on the place, but you should never have any faith in the promises of a bull. The dangerous bulls are those with whom familiarity of the farmers' boys breeds contempt. Some day, in a moment of ungoverned passion, he will realize his power, and then there is danger of a funeral. There is never any confidence to be placed in a bull, or in a man who cannot control his temper. It is hard to tell which of these is the most dangerous.

Just before milking, the udder and adjacent parts should be moistened with a damp cloth. The milking should be done with dry, clean hands. The clothes of the milker should also be clean, although that is not generally the practice.

CHARCOAL FOR HOGS.

The economical and satisfactory way of securing a good supply of charcoal for hogs is as follows, says the Iowa Homestead:

Where one has a supply of corncobs it is not a difficult matter to make up a batch of charcoal. Dig a pit sufficiently large to hold the amount of cobs to be used at one burning. Usually this pit is circular and may be made four or five feet deep. However, we have had good success in using a trench about two feet wide, four feet deep and any length.

Start a fire with shavings and kindling in the bottom of this trench and gradually pile on the cobs. Care must be taken not to smother the fire—just allow the flame to show through the surface all the time until the pit is full, then place a tight covering over the top. Wood will not do, as it will burn out. It generally pays to have on hand for this purpose an old piece of sheet metal of some kind. Build a little earth around the edges, so as to absolutely exclude the air.

When the charcoal has cooled off it may be sacked up, and usually it is advisable to mix with it a little salt. A mixture composed of one barrel of charcoal to one pail of salt is usually eaten eagerly by hogs. Where it is desirable to use such a mixture for the prevention of worms, a little copper sulphate may be dissolved in water and then sprinkled on this mixture, so as to cause its uniform distribution. The whole mixture is usually placed where hogs may have access to it at all times. It is not difficult to extemporize a self-feeder so that the mixture is kept dry.

WRAPPING BUTTER SQUARES.

The question is often asked if it is better to wrap butter with wet parchment paper than with dry paper. The answer is variously given, says the Farmers Review. Some butter makers in creameries wrap their butter in wet papers for the following reasons: The butter will not stick to the paper so much and the squares can be wrapped more quickly with wet papers than with dry, as they bend more readily. When wet paper is used it could have been soaked in boiled brine and so be free from spores. This helps to keep the butter from being affected by spores on the paper. The men that wrap dry claim that while it takes a little more time to do the work of wrapping, the package looks smoother as the wet paper wrinkles on drying; also the brine in the butter seems to work through the parchment paper more when it has been wet, as is seen by the salt incrustations on the sides of the squares. If the butter is to be used at once there is no reason for using wet paper, but if the butter must be kept a long time it is doubtless better to use parchment paper that has been well soaked in brine or some other anti-septic solution.

COLLAR OF THE WORK HORSE.

Next to a well fitted collar salt water and borax wash is the best treatment to toughen the tender skin and save pain and trouble with shoulders. For years we have made it a custom to send work mules and horses to the harness maker, where each could be accurately fitted in the spring with a new collar if needed. It pays to fit the collar to the individual. We have thin necks and thick necks to fit, and the same style or filling will not fit all—to say nothing of measurements from top to bottom. Do not make the serious mistake of taking up or letting out hame strings to force a bad collar to fit. It won't do it.

Manure is one of the incidental products of sheep raising and its careful saving and intelligent application will add much to the profit.

NOTES BY A CULTIVATOR REPRESENTATIVE.

Dairy Inspectors Beware.—As I stood admiring a herd of Jersey beauties, just north of Compton, the monarch of the yard, huge of limb, shaggy of brow and fire in his eyes, hurried up to the fence and "squared away" for action. I was on the safe side of the enclosure. It was a challenge. Perhaps he mistook me for a dairy inspector, or a member of the board of health who had been writing unfavorable reports about the sleek and clean members of his harem. I have visited a large number of dairies near Compton and Hynes, and almost always found the stables and yards in fine order.

* * *

An Invitation.—Mr. Yeoman,s of Compton, says any dairy inspector is invited to visit his premises without previous notice, eat at his table and inspect his dairy, and if he does not find things as neat as his own he will give him the best cow in the herd. As I had the pleasure of eating at his table and inspecting his cows, I consider his offer a prefectly safe one.—O.. Los Angeles.

FOR CAKED UDDER.

L. S. Kirkpatrick, of Hynes, says that when a cow comes in at night with a partially caked udder, he has always found that an immediate application of hot lard with a little turpentine will soften up the caked part, and restore it to its normal condition. He does not claim this as any new discovery, but it is sometimes well to refresh one's memory with remedies used fifty years ago.—O.

BAD TEETH.

Regarding preventing horses turning their heads from feed box and losing much of the grain while eating, a writer in the Dakota Farmer gives plans for constructing feed boxes so as to prevent horses from turning their heads from the feed boxes while eating. "I have a plan which I believe is better than any offered so far as it removes the cause. Turning the head to one side while eating is almost a sure sign of defective teeth and a veterinarian should be called and the teeth attended to. This will usually remedy the matter.

HOW TO SKIN A HORSE.

This is my way of skinning a horse. Rip clear from chin to end of tail bone, skin back the neck and belly six or eight inches, skin out the legs clear to body, skin the head out, tie a loop knot around this with strong rope to back of the ears, to hitch team to. Tie the animal's head to a post and pull in the opposite direction. If your team stays by the job it will not last long and the hide will come off tail and all and there will not be any holes in it. There is nothing nicer in the line of robes than a horse hide if taken off in the right season and properly tanned. I have seen some robes that were considered worth more than the horse that wore them.—Dakota Farmer.

Sheep and lambs are often deceptive to the eye. A short legged, short-bodied sheep is often heavier and will produce more wool than one that looks to be twice as large. Great, coarse-looking sheep are not desirable.

NO MORE FREE GRAZING.

California forest supervisors have received instructions that after January 1, 1906, they are to make charges on all stock grazing on the forest reserves. Sheep and goats will not be permitted on California preserves. The charges are to be, at the outset, according to instructions, a minimum of from 25 to 35 cents per head for cattle and horses for the regular summer grazing season and from 35 to 50 cents per head for the entire year. These prices to be increased gradually when warranted by market conditions.

EVERY BLOCKHEAD CAN'T RUN A DAIRY.

In a series of articles on dairying the San Francisco Call makes an appeal for more attention to dairying and urges impressing upon new comers its advantages and the advisability of taking up that line of work. It says: "This advice may well go to the eastern settlers who are flocking in. Not many of them are skilled in fruit growing, and none have knowledge of the peculiarities of horticulture in California, but nearly all of them know the cow and are familiar with dairying. They find here in alfalfa the best milk food in the world.

Now then, the Call means all right, but there is a slight implication there that 'most anybody knows enough to run a dairy. So it may be said that any one knows enough to dig a hole and shove a tree into it; but that does not constitute successful horticulture. True, "nearly all of them know a cow" in that it usually has "horns on its front end, has four legs, one on each corner, and a tail on the other corner." We wish it were true that "nearly all of them know a cow," in a different sense.

There are wonderful possibilities in California dairying. To develop these possibilities it takes intelligence of a high grade. Let us encourage that class to engage in dairying, for there are already enough of the others.

Don't keep cows in same barn with other stock. Time is money; therefore the barn should be convenient for cleaing out, for feeding and for getting cows in and out. It should allow an abundance of sunshine.

For ventilation, have windows hinged at the bottom and open in. We salt in boxes in the winter time, where the cows have access to it at all times. In summer put it into the feed at the rate of two ounces per cow per day.

Every young man who contemplates following the dairy business should take a course at the agricultural college. In addition to the scientific knowledge obtained there, it will engender studious habits, which always insure success.

It is generally acknowledged that every dairy farmer who wishes to keep the average yield of his herd up to the mark and wishes to try and improve the same, ought to test the animals periodically in regard to their milking power.

The advancement made in dairy science during the last few years is wonderful and the future has still brighter things in store for the up-to-date dairyman. These facts are now before the farmer and he must heed them or fall behind the procession.

For best results hogs must be kept free from lice. Dipping is growing in favor and some day will become the rule.

Six pounds of skim milk is equal in feeding value to one pound of shorts. They make a fine combination fed together.

The weather and crop conditions for the week ending August 7 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—The weather was clear and cool for the season until near close of the week, when higher temperature prevailed. Foggy nights and mornings were frequent in the coast districts. The overflow of the Colorado river in the Salton basin and the Imperial district has caused some damage, especially at Calexico, where 1000 acres were flooded.

Grain harvest is completed in many sections and progressing rapidly in others. Threshing will not be finished for some time. Wheat, barley and oats are reported below average in nearly all parts of the State, possibly excepting portions of Southern California, where the yield is the best for several years. Barley has yielded a very fair crop in portions of the Coast and Bay sections. Hops are improving and making good growth; picking has commenced in the vicinity of Sacramento and the first bale of new hops was shipped east during the week. Hay baling and sugar beet harvest continue. Beans, corn and vegetables are doing well. Dry feed is plentiful in most sections and cattle are in good condition.

All varieties of deciduous fruits are ripening rapidly and large shipments are being made. Canning and drying are progressing. The yields are better than anticipated in many sections, though generally below average. Grapes are somewhat backward, but continue in good condition and are maturing quite satisfactorily; the crop will probably be large and of excellent quality. Citrus fruits, olives and walnuts are in good condition.

Eureka Summary—The acreage in oats is larger than last year; quality excellent. Hay is being stacked; quantity and quality never better. Early varieties of apples are in market; crop average.

Los Angeles Summary.—Cool, cloudy weather along the coast continues. It is favorable for beans, but retards fruit drying. Conditions in the interior are favorable for hay baling and threshing. Honey harvest is about over, with a successful season.

EDITOR'S QUESTION BOX.

Water-glass—(Constant Reader): I put some eggs into a solution of ten per cent water-glass about two months ago. It now seems to be congealing, or forming a paste over the top and on the eggs. Is it going bad? Should I take the eggs out and wash them? Or had I better use them now? I wanted to keep them for winter use.

Answer—The water-glass is all right. It forms a coating on the eggs and in that way preserves them. Your eggs, if fresh when put into the solution, will come out good a year hence, but you must be careful to keep them two inches below the surface, weighted down with a plate or board and large stone. A few days ago I met E. H. Fosdick, a very clever analytical chemist of Los Angeles, and had the pleasure of discussing the good qualities of silicate of soda (water-glass) with him. He asked me why I preferred water-glass to the lime and salt solution, which has been found very satisfactory. I told him that, first, I had tried the silicate of soda myself for three year and found it a perfect preservative; secondly, experiment stations had decided that it is the best preservative known; and, thirdly, I had found that the lime and salt solution would not always permit of the eggs being beaten up light for cooking. I had used this method for many years in the East, and whilst it kept the eggs very well, it was apt to partly cook the white. He thought that the silicate of soda would do the same, and he also feared that the eggs might taste of the soda. I have never noticed any taste of soda, but I have of the lime. The experiment stations recommend a ten per cent solution of the silicate of soda, and, in view of the possibility of its giving a slight taste to the eggs (which I have never discovered) it might be well not to make it any stronger.

* * *

BROODER CROWDING.

Editor Cultivator: Will you please tell me through your paper how to arrange young chicks to sleep at night. Mine pack and consequently many smother. I had them in a brooder and kept it the proper temperature. Is it necessary to have artificial heat through the night for chicks, or do they make heat enough when together in a box to keep them warm?

Is it all right to keep rooster of one's own stock, that is, shall I keep roosters out of my own brood or should I get roosters elsewhere for breeding. By reading the Cultivator and carefully following your directions as to feeding and caring for poultry, I have been able to get, daily, half as many eggs as I have hens all through the moulting. Always before I averaged one-sixth as many eggs as hens. The Cultivator is the most welcome guest we have.—Mrs. J. W. Wittman, Santa Rosa.

Answer.—I had similar trouble with young half-grown chicks. I circumvented the little perversities by making it very uncomfortable for them to crowd. I made a little floor, or rather a little platform of laths nailed, the space of a lath apart, on stringers three inches wide. I placed the ordinary perches about four inches above this floor and they found the lath floor so uncomfortable that they soon took to the perches. If you do not stop them crowding you will stunt the growth of the whole brood.

The second question I cannot answer as I know nothing whatever of your breed, not even what kind of fowls they are, nor how closely bred. You can easily see how difficult it would be for me to guess at the proper way for you to breed them.

* * *

DOUGLAS MIXTURE.

How often should the Douglas mixture be used. I have heard it well spoken of and saw in your paper how to prepare it; also the right quantity; but there was no specified way of how often to use it. Is it used more for a tonic, or a preventive of disease?

Is kerosene emulsion good after a few days standing? I think it very good for mites.

Do you think Darling's beef scraps as good as any brands and how much should be fed to 100 hens and how often?—Mrs. F. P., Santa Rosa.

Answer.—The Douglas mixture is both a tonic and a disinfectant. You can give it at moulting time for one week every month. Or if you have roup or any infectious disease in your yards you can give it for a month without harm, as a preventive.

Kerosene emulsion is good for several months if properly made, that is if it is churned sufficiently (about twenty minutes).

I use Darling's beef scraps and think them as good as any. Usually feed half an ounce per hen every other day, or one ounce when they are moulting.

MORE ON SUMMER HATCH.

Along the same line as Mr. Harrison's article in a recent issue, we note the following from the Poultry Gazette:

"It all depends on circumstances. If you have been successful in getting out a large number of early chicks and desire to continue hatching during the summer you must arrange to keep the late chicks entirely separate from the early ones. If all are allowed to run together the early ones which are by this time of good size, will trample over and crowd back the late chicks, with the result that the latter do not get the amount of feed necessary to force their growth. Then, too, the breeder who has a large number of early chicks generally loses interest as warm weather approaches, and does

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

When writing advertisers mention Cultivator.

not look after the welfare of the late broods as carefully as he did those that hatched early in the season. He is not so particular about keeping the lice down. When this is the case late chicks are of but little value.

But now let us look at the other side of the question. Suppose you do have a large flock of early chicks and as poultry raising is your business—it is the way you make your living and get money for the children to go to the circus—you desire to hatch during the summer in the hopes of having enough stock to supply all demands. Your heart is in the work and naturally you will provide suitable quarters and range for your late broods where they will not be bothered by your half grown chicks. You care for them as carefully as you did the first little ones you took from the nest or incubator, and what is the result? They thrive and grow, and when early winter arrives they are pretty big chickens. And then when the December and January shows are on and many of your early cockerels are beginning to look a little coarse and the early pullets have lost some of their grace and beauty on account of having commenced to lay, you go to your flock of summer hatched chicks and pick out your cockerels and pullets that will carry off the ribbons. This is not an idle dream. It is facts we are giving you. This has been proven many times.

There is one more view of this summer hatched chick question. Every year there are a great many people who buy a setting or two of eggs and the chicks they get from these are the only ones they raise. Many times these people, who do not have incubators, are not able to obtain setting hens until late in the season, hence they must hatch their chicks during the summer months or go without. Now, there is no good reason why this class of poultry raisers should not buy one or two settings of eggs and get their chicks out during June and July. It is folly to discourage them. Not having any other young chickens to care for they will naturally take a great deal of interest and give their summer hatched chicks the care they will require to bring them out in fine shape.

So you see it depends on the people who are to raise the late chicks. It depends on circumstances. Summer hatched chicks are all right for the right people.

GROWING SQUABS FOR MARKET.

From a bulletin on squab raising issued by the Department of Agriculture we take the following extract:

"Poultry market men declare that for choice squabs it is necessary that a light plumaged breed having good size be selected, according first place to the white homing pigeon. These magnificent birds are large and healthy, are good workers, always active and hunting about like the Leghorn fowls; are the best feeders; are of quiet disposition when properly mated; and their eggs are seldom infertile. For these reasons I consider the straight homers par excellence among all the pigeon kind for squab farming." The author thinks well of the Dragoon, a blue plumaged breed, and states that a cross of the homer and Dragoon produces an excellent squab. The Duchess is preferred by some, but this breed has the disadvantage of possessing feathers on the legs. The runt is another breed often used for squab raising, probably on account of its tremendous size, but it is not a prolific breeder and is further handicapped by the fact that its meat is dark. Straight bred homers are said to be hard to obtain. Squabs of this breed are quick maturing, probably requiring less time than any other breed, and breeding stock therefore commands good figures. The beginners should endeavor to start with good stock, securing the assistance of an experienced pigeon raiser in selecting it, if possible.

* * *

Mating and Breeding.—Upon the important matter of mating the bulletin referred to says: "Unless the birds are known to be mated they should not be placed in the breeding quarters. Hence, a mating house, fitted with nest boxes, is necessary when but few birds are kept, and in this house they should be placed until they begin to carry building material and build nests; then, and not until then, they may be transferred to the permanent breeding house. When but few birds are to be mated a box with a wire netting front and a partition can be used, or any small room can be improvised."

To prevent the disastrous results which surely follow in the wake of careless breeding or inbreeding, the author advises marking and keeping a record as follows: Before the birds are placed in the breeding house each bird should be banded. Open numbered bands can be purchased by dealers at about 1 cent apiece in quantities of 100. Squabs intended for breeding must be banded in the nest before able to fly, as by so doing nest mates can surely be distinguished. If closed bands are used they can only be put on when the squabs are quite small.

It is advisable to keep a record book and enter the number of each bird, noting the sex, color, and any other distinguishing mark, so that the record will accurately describe the bird. Then should any bird die the record will show its sex and another mate can be substituted, or the remaining bird can be taken and placed in the mating coop until again mated.

If a beginner is in possession of a flock of fifty pairs of selected birds, well mated, this record will make easy the matter of increasing his flock intelligently. Young birds, from the best breeders only, should be selected and banded as directed. At the age of six weeks these youngsters should be taken out and placed in a separate coop, and in this coop none but young stock should be kept. All young birds before being thus put in a separate pen, should have all tail quills plucked out, because there is less mortality among birds so treated while attaining their growth.

Standard Bred S. C. White Leghorns

EXTRA LARGE BIRDS AND HEAVY LAYERS. Eggs, $2 per 15; $8 per 100; $60 per 1000 from January until July only.

It is well for the beginner to keep a record of the squabs as produced, numbering each nest and entering in the records the birds working in each nest and the number of squabs produced. Some pairs will produce ten pairs of squabs a year, while others may yield only five. The record will enable the breeder to save young breeding stock from his prolific breeders only. If the bands are numbered consecutively and the birds are banded before leaving the nest, the nest mates will always have consecutive numbers. It sometimes happens that a nest will only have one bird in it, in which case the record should indicate that fact.

STORAGE EXPERIMENTS.

Experiments have been made by Director Strauch of the Neisse Agricultural school, Germany, with various methods for keeping eggs fresh. Batches of twenty fresh eggs were each subjected to treatment by different methods at the beginning of July, and they were examined at the end of February. The results are most interesting and proved that, if properly treated, eggs may be preserved for a long time. The twenty eggs kept in brine were all unfit for use; they were not decayed, but unpalatable from being saturated with salt. In the other treatments the results were as follows:

	Pct. Spoiled.
Wrapped in paper	80
Kept in a solution of Salicylic acid and glycerine	80
Rubbed with salt	70
Packed in bran	70
Painted with a solution of salcylic acid and glycerine	70
Immersed in boiling water from 12 to 15 seconds	50
Treated with a solution of alum	50
Kept in a solution of salicylic acid	50
Coated with soluble glass	40
Coated with varnish	40
Coated with collodian	40
Rubbed with bacon	30
Packed in wood ashes	20
Treated with boracic acid and soluble glass	20
Treated with permanganate of potassium	20
Coated with vaseline and kept in lime water	All good
Kept in soluble glass	All very good

It is important to bear in mind that the eggs must be treated when perfectly fresh.

AN EXPERIENCE WITH RUNNERS.

Editor Cultivator: As I have received much valuable information through the Cultivator, will give my experience as a beginner. We bought a trio of Indian Runners; they had not laid yet, they told us (likely had not been well fed.) They soon commenced to lay. Wet set them (after perhaps the first half dozen) and got nine out of twelve eggs. Then we bought five more, four ducks and a drake. That made us six ducks and two drakes; we set them under hens mostly, setting three or four hens at a time, twelve eggs under each. Set incubator once on 60 eggs, forty-four being fertile; kept it the same as for hens' eggs, excepting sprinkled the eggs the last week at noon each day. Only hatched seventeen from forty-four fertile eggs. Was not satisfied with that, so set seven hens on eighty-four eggs, and when they began to pip, put in incubator at 103 to 104 degrees. Hatched seventy-eight of the eighty-four (helped two out). Who can beat that?

Sometimes we left the hens to hatch them out, not paying any attention to them, more than to notice they did not get an egg mashed over the rest. They never hatched less than nine, and sometimes eleven, from twelve eggs, but occasionally would get one mashed. We took them out of nest two or three times a day as hatched.

We set hens in box with slat coop over, putting water and feed inside the first few days, After that, let hen off each day for feed. Have raised all in outdoor brooder, which we like very much, except the first hatch, which we tried with mother hen. Found her too much trouble at feeding time, and no good except to be with them at night. Have 125 or more ducks, good size.

This has been my first experience, but think I have been quite successful. Hope this will be some encouragement to others.—Mrs. W. S. M., Escondido, Cal.

To hurry the chicks from the incubator to the brooder invariably means a set back," writes one who has learned this by experience. His advice now is, "Give them time to dry off and get on their feet."

It is a good plan to get rid of the roosters, old and young, as soon as possible. The old ones are eating their heads off and the young ones should not be kept long after they reach marketable size.

THIS IS TO CERTIFY that I have sold all of White Leghorns, including my best breeders, to Mrs. P. L. Updyke of Fullerton, Cal. I can recommend the said parties as straightforward, honorable people who will do all they agree to.

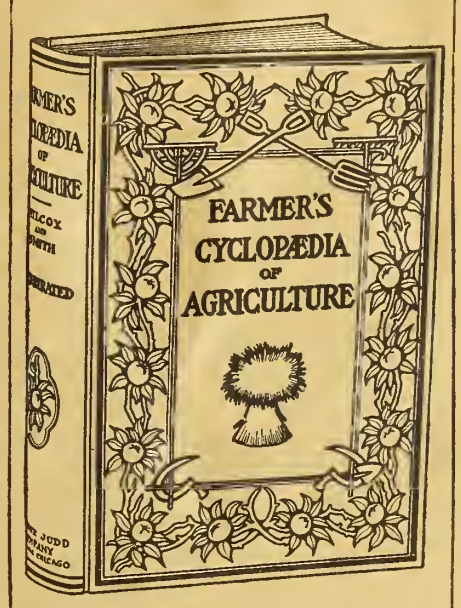
Farmer's Cyclopedia of Agriculture



A Compendium of Agricultural Science and Practice on Farm, Orchard and Garden Crops, the Feeding and Diseases of Farm Animals, Dairy Farming, and Poultry in the United States and Canada

Authors: EARLEY VERNON WILCOX, Ph. D.
CLARENCE BEAMAN SMITH, M. S.
Assistant Editors in the Office of Experiment Stations, United States Dept. of Agriculture

The World Moves

and whoever would not be left behind must lay hold on every means that enables him to move with it. As a basis of one's efforts nothing is more essential than the possession of a good work of reference

Adapted to the Conditions Peculiar to California and Adjoining States

The Farmer's Cyclopedia embodies in its many articles, most of the results of years of painstaking work at the California and neighboring State Agricultural Experiment Stations. It is thus, in effect, both a digest of local and state experience, and a compendium of general knowledge, all of which will prove of indispensable helpfulness to everyone in this section.

The Last Twenty Years of Progress

have measured more changes and recorded more advances in every branch of agricultural science than have been achieved during the hundred years preceding. During all these years no reference book adequately covering the subject has been issued.

The plan of this work is most comprehensive. Every article has received the most careful preparation at the hands of the authors, who have enlisted the co-operation of the highest authorities in the various departments. The greatest educators of the world, representing every branch of agriculture, here unite in one immense faculty to present directly and plainly the pertinent facts of their specialties. Every statement is authoritative and absolutely reliable.

If you wish to know about field crops, garden vegetables, fruits, nuts and other economic plants, farm animals, dairy farming, poultry, also manures, fertilizers, principles of feeding, soils, drainage, irrigation, spraying, veterinary medicines, etc, etc, it is here. Everything concerning farm matters is treated with great thoroughness, though without undue fullness. We claim for it the unique distinction of presenting for the first time, in a carefully arranged and perfectly accessible form, an accurate summary of every subject of interest to farmers, etc.

Over 6000 Topics Indexed
A Wealth of Illustrations

An important part of this work is its very complete and elaborate index, with cross-references under both scientific and common names, so that any information wanted can be found at once. There are between 6000 and 7000 topics covered in these references, making the most perfect index to agriculture ever attempted. It contains 700 royal octavo pages (9½ x 7 inches) and nearly 500 superb half-tone and other original illustrations. Type, paper, printing and binding are all in the highest style of the bookmaker's art, worthy alike of the well-qualified authors, the enterprising publishers, and the industry of agriculture.

PRICE IN HALF MOROCCO, $4.50

To Cultivator readers we make this proposition:—Fill out and sign the enclosed coupon and mail to this office and the book will be delivered postpaid at once and your Cultivator subscription advanced one year.

CUT OUT AND MAIL THIS COUPON AT ONCE

CULTIVATOR PUB. CO., LOS ANGELES, CAL.
Please enter my name for one year (NEW or RENEWAL) and send me the Farmer's Cyclopedia of Agriculture, half morocco. For both together the price to be $5.00, which I agree to pay as follows: $1.00 on the first day of next month and $1.00 on the first of each of the succeeding four months. Until the $5 is paid in full title to the Cyclopedia to be vested in you.

P. O..... STATE

THE PROCESS OF FIG CURING.

(Continued from First Page.)

they are dumped into the sweat boxes and are ready for delivery at the packing house. The cost of drying is in the neighborhood of $15 per ton.

* * *

The Calimyrna.—The gathering of the Calimyrna figs is done practically in the same way as with the White Adriatics, with the exception that the figs drop from the tree in a more uniform condition and if any fig does not drop readily when fully matured, a slight jar on the branch will cause it to fall. When the figs are carted to the drying ground, the are dumped from the boxes into a perforated tin bueket holding about one picking box of figs, and they are then immersed in a boiling brine for half a minute. The brine is made by dissolving six ounces of salt in a gallon of water. The figs are then spread on the trays and exposed to the sun. The method of handling on the drying ground is practically the same as for the White Adriatic except that they are exposed for a shorter time. In the height of the drying season they are turned over and the trays are then stacked, the hot air circulating through them after this being sufficient to dry them properly. From the drying ground, the figs are either dumped into sweat boxes, or are placed in a pile in a room in the drying shed built of tongue and grooved lumber. Here they remain for a number of days, being turned occasionally so that the moisture in them will be evenly distributed. The preparations before taking them to the packing house which follows are the same as for the White Adriatic.

The naturally white, silky appearance of the skin makes sulphuring of this fig unnecessary.

The black fig requires no dipping and no sulphuring and for this reason can be handled more cheaply than any other variety. The fig should be merely placed on the trays and when dried dumped into sweat boxes.

Another method of handling the White Adriatic and Calimyrna figs, and which has many advantages over the plan usually followed, is not to expose the figs on the trays until entirely dry, but, when half dry, to dump the figs on to muslin sheets, about five by seven feet. A sheet of this size will hold about one hundred and fifty pounds of fruit. As soon as the sheet is filled the four corners are drawn up together and twisted until the figs are completely enclosed. This makes a ball or sphere of figs in the sheet which is then rolled over with the twisted flap underneath. The weight of the figs prevents the flap coming loose. A bed of straw should first be made so as to prevent the sheets from becoming covered with dirt. These sheets containing the figs are opened each morning and the figs are spread out over them. They are exposed to the sun for a couple of hours, when they are again rolled up. The opening of the sheets and exposing of the figs continues until the leathery condition of the fruit shows that it is dried sufficiently.

This method has a number of advantages, among them being the fact that not so many trays are necessary to handle the crop, and another great point is that the figs are much softer and more pliable, and the quality as a whole is very much better. The following treatments which the figs receive, have already been fully described.

* * *

In the Packing House.—The first treatment which the figs receive when taken into the packing house, is to grade them into four sizes the smallest figs are never packed and are designated as one crown, the largest as four crown. After leaving the grader, they are dumped into bins, each grade being kept to itself. Before packing, the figs are run through a dipper; here they are given a bath in a hot brine and are also subjected to a jet of steam. This heats the figs through, cleans and softens them and also kills any insect germs which may have been deposited on the fruit on the dry ground. The figs are then carried to the packing tables, and are taken in hand by women and girls, who supple and flatten them out, and split them open on the back from the eye to the stem. A small knife is used for this purpose. The figs are then placed in wooden forms, which are made to hold either one-half or a pound of fruit. Each form has five compartments. After leaving the packers' hands they go to the wrapping tables. Here the bricks are taken out of the forms and wrapped in parchmyne paper, which is held in place by a neatly lithographed band, wrapped around the package lengthwise. Ten of these packages are required to fill a box and figs packed in this manner are styled by the trade as bricks. The other method of handling is to pack them in paper boxes like those used for seeded raisins, each package being designated as cartons. During the height of the packing season from two hundred to three hundred men, women and girls are employed in the larger packing houses and the daily output is from three to four thousand ten pound boxes.

The Calimyrna Figs are packed in identically the same manner as the Adriatics, with the exception that they are merely steamed in a large wooden box, lined with galvanized iron. The fruit being of a higher grade requires more careful manipulation although the actual expense of processing is even less than for the common figs.

* * *

Benefited by Pruning.—There is a widespread fallacy that fig trees should never be pruned. A fig tree which is not growing thriftily is benefited by pruning; the bearing qualities of the tree are not impaired in the least and in addition to this, the figs are of better quality and very much larger.

* * *

A Great Future.—It is not my desire to take up the space in your valuable paper by any personal reference to myself relative to the Calimyrna fig. It is a fact, however, that many people in the very heart of the fig district of California are skeptieal even to this day as to the suceess of the Calimyrna fig. When the little fig wasp was established five years ago, had the owners of White Adriatic fig trees grafted their trees over to the Calimyrna, Fresno would today be shipping at least five hundred tons of these magnificent figs and would have established the reputation of being the great fig center of California. The insect is here to stay, its five years residence in California is evidence of that fact. The trees bear just as heavily as the White Adriatic, and simply beeause there are apparently not so many figs on the tree does not prove that the weight is not there when the figs are dried. From twenty-five to thirty per cent of the White Adriatie figs delivered at the packing houses are one crown goods not fit for packing, while in the Calimyrnas the average is less than five per cent.

* * *

A Profitable Industry.—California has the fig business in the palm of her hand and if the fruit growers can only be made to realize of what importanee and how profitable the industry will be to them if carried on along proper lines, they certainly cannot afford to plant anything but the best.—Geo. C. Roeding, Fresno.

* * *

The great work which Mr. Roeding has done in introducing the Blostophaga and in persistently staying by the fig industry until it is placed upon a better footing than ever before entitles him to greatest credit for his tireless work. As before noted in the Cultivator, the practical work of introducing the little wasp which has been the means of introducing the fertilizer pollen to the Smyna fig (which Mr. Roeding sells under the copyrighted name of Calimyrna) was the one thing needed to make the industry a success. To secure that, Mr. Roeding made a trip to Asia Minor and ultimately accomplished his purpose. He is to day the largest grower and shipper of those figs in the country and is succeeding in making a great name for his copyright brand, "Calimyrna."

UNITED.

English Rector (to parishioner)—"Good morning, Thompson; I hear you have a son and heir?"

Parishoner—"Yes, sir; our household now represents the United Kingdom."

Rector—"How so?"

Parishioner—"Why, you see, I am English, my wife's Irish, the nurse is Scotch, and the baby wails."—Harper's Weekly.

A TOAST TO THE FARMER.

Here's to the man who rises with the lark,
Early in the morn while still it is dark,
To furrow and plant, to protect and reap
On hills that are high and in valleys deep,
Though horny of hand and plainest of clothes,
Nature and nature's laws the best he knows.
The clear sparkling dew-drops on all the blades
Flirt with the morning sun's first kissing rays;
Nature's color, new and fresh o'er night
Man's own labor to aid and finish aright.
Blessed is he on his own acres broad,
To reap the harvests his own hands have wrought;
Content, what ere possessing, he best knows,
Who labors and waits in trust—God repose.

—Eugene J. Sharadin, Perry, Calif.

Queries and Suggestions

ROOF PAINT.

We have an inquiry from Santa Rosa for roof paint, which was given in the Cultivator some time ago, date of paper having been lost. We ask our subscriber to refer to the issue of June 23d, where a crude-oil-Prince's brown-metallic mixture is given and recommended as being an excellent and cheap roof paint.

CHICKENS DYING.

Inquirer from San Diego has communication regarding chickens dying off which has been answered by Mrs. Basley by mail.

BUFF WYANDOTTES.

Editor Cultivator: Please inform me where we can secure Buff Wyandotte eggs.—E. C., Riveria.

O. S. Hoffman of San Jacinto can supply you. We do not know of any others near Los Angeles, but if there are any other breeders of that variety they should have their announcement in the columns of the Cultivator.

YOUNG'S BOOK.

An inquirer in the Cultivator recently asked for address of publishers of Young's Book of Secrets. H. P. Underwood, of Holtville, writes us that he has one which he bought from H. J. Wehman, Park Row, New York.

ALFALFA NOT DOING WELL.

Editor Cultivator: I have an alfalfa pasture divided into checks fifty feet square, flooded by pumping once after each cutting. In almost all of these checks there is a spot which does not do well. Grows five or six inches high while the balance does finely. What is the trouble?—Arthur C. White, Stockton.

It is impossible to answer such a question without knowing more of the particulars. The fact that the alfalfa grows five or six inches high while the rest grows taller would look as if there had been some fault in laying the contours or leveling the surface so that the section in question may want for water. Or those particular spots may be underlaid with a coarse gravel permitting the irrigation water to leach away, there being sufficient to start the alfalfa but not to keep up the growth to the full height which it would naturally grow to. On the other hand, if the land is heavy and has probability of alkali, that might possibly be the trouble, although we think not. If it be the fault of the leveling, of course the remedy is apparent. If the fault of an underlying bed of gravel which leaches away the water, it would be impossible to control. If the soil is sandy and infertile, fertilize.

TROUBLES WITH TOMATOES.

Editor Cultivator:—Under separate cover, I herewith mail you tomato twigs and leaves. Will you kindly tell me through the columns of the Cultivator what is the matter with them? I have never seen tomato wilt and would like to know what it is like. They grew finely. But soon one plant and then another, got to look like these samples, and the blossoms drop. I am afraid the whole patch will become affected. Will you please tell us what to do for them, if there is any known remedy?—Mrs. John Gottenberg. Monticito.

Also, Mr. Laughlin, of Hesperia, reports his tomatoes, while apparently strong growing and healthy, suddenly turn yellow and die.

The vines sent by Mrs. G. plainly show "wilt," or tomato blight. Those of Mr. L. we cannot be so sure about, but imagine it a similar trouble. Probably in either case the early application of Bordeaux would have saved them. Diseased plants may now be too far gone, but the healthy ones near them may possibly yet be saved. The Bordeaux mixture is used by most tomato growers, whether there is any indication of disease or not, some working with spray pumps, others with sprinkling wagons and covering the whole field while the plants are young.

Owing to the general interest at this time we quote as follows from a bulletion of the Texas Experiment station:

Tomato Wilt.—The first intimation of the presence of this disease is the sudden wilting of the plant. The mysterious manner of attack and the feeling of helplessness experienced in the face of it causes the wilt especially to be dreaded by the grower. The disease, despite the awe it occasions, is not so serious as it seems, for though it "takes" and utterly destroys plants here and there, it rarely involves any considerable portion of the field, provided ordinary precautions are taken for its prevention.

The wilt is caused by bacteria, minute plants, which grow, multiply and flourish in the tissues of the tomato and so pack themselves into its cells that it becomes no longer possible for the sap to circulate freely, whereupon the leaf or plant collapses and the "wilt" results. The disease is spread from plant to plant largely by leaf-eating insects. These pests after eating diseased tissues carry the germs on their jaws to healthy plants, thus disseminating the contagion. The remedy naturally suggests itself, simply poison the leaf eating insects. This is readily accomplished by adding four ounces of Paris green or two pounds of arsenate of lead to every fifty gallons of Bordeaux, when you spray for the leaf spot. As a further precaution wilted plants should be pulled up at once and burned, and at the end of the season the old plants should be destroyed by fire. In case the wilt has been troublesome tomatoes should not be planted on the same field the following year, it being supposed that the germ lives over in the soil. Avoid exeessive nitrogen in the fertilizers used, as soft succulent plants are most easily affected by the disease.

The formula for the Bordeaux which has been given many times, is as follows:

Copper sulphate (bluestone) 5 pounds.
Fresh lime ..... 5 pounds.
Water ..... 50 gallons.

Dissolve the copper sulphate (bluestone) in a barrel containing ten or twelve gallons of water. Slack the quicklime and thin to a creamy whitewash. Pour the whitewash very slowly through a wire screen into the copper solution. Stir the mixture thoroughly, and add enough water to make fifty gallons in all, or better, pour lime and copper solution at the same time into the water, stirring hard during the pouring. Stir occasionally while applying to the trees.

In the preparation of the Bordeaux mixture it is necessary that the ingredients should be mixed in a wooden vessel. If an iron vat is used the copper will go to the iron and the effect of the spray is largely neutralized. Apply the remedy cold and as soon after it is prepared as possible. Never allow it to stand over night.

This may be applied by the ordinary hand spray pump or from a sprinkling pot, if a very small quantity or in any way to be sure that they touch nearly all parts of the plant. Apply to the healthy looking plants because they are probably the only ones that will be saved. Where the disease has already appeared, it is upon the inner tissues of the plant where it will never be reached by any fungicides.

PRUNING ACACIAS.

Editor Cultivator: We planted some acacias about seventeen months ago. They have grown to be about two inches in diameter at ground and some twelve to fifteen feet high. They are tied to stakes about four feet above the ground, but some of them are bent away by the wind above this. We are thinking of cutting them back in order to straighten them. Will it be best to do this and if so, when should it be done.—E. S.

It will perhaps be wise to top back the trees and if so would suggest that it be done immediately. This for the reason that the topping will probably force out a large number of side shoots which should have time to make their growth and harden before the cooler weather of winter. We take it your acacias are the Melanoxylon or black acacia, and not especially susceptible to frost, but if pruned later and if full of sap and succulent growth might be injured by such weather as might come. If they could be topped somewhat above the top of the stakes, for we note you say that they are tied four feet, we think it would be well, for street trees should really be branched higher than that in order that the later prunings may raise them above pedestrians' heads.

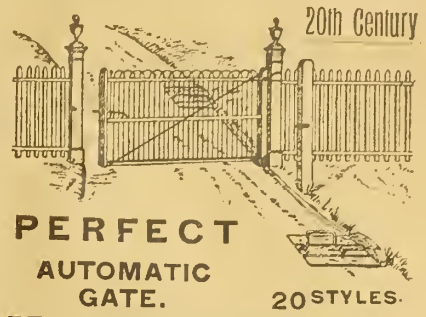
MAKING OLIVE OIL.

A inquirer from Highland wishes information as to the manufacture of olive oil. This will be treated in a separate article within the next week or two in the columns of the Cultivator, and while it is hardly probable that home manufacture of oil will ever be very profitable because of the fact that difficulty in making good oil without knowledge of the various details of the business will be a preventive of many entering into it, we hope, however, to give some hints which will be of value to our inquirer.

Also another inquirer wishes information regarding reclamation of alkali lands. This will also be touched upon later.

DYING TURKEYS.

A Ceres subscriber wishes information regarding turkeys dying in large numbers when nearly two-thirds grown. Mrs. Basley will answer more at length next week. Meantime, thoroughly disinfect, keep pure water before them and give each a liver pill.



PERFECT AUTOMATIC GATE. 20 STYLES.

Money Refunded If not satisfactory or as represented. ***Works 365 days each year. NO OILING***—ten minutes each year and 10 to 20 cents expense—***no more.***

OUT IN THE FIELDS.

The little cares that fretted me,
I lost them yesterday
Among the fields above the sea,
Among the winds at play,
Among the lowing of the herds,
The rustling of the trees,
Among the singing of the birds,
The humming of the bees.

The foolish fears of what might happen—
I cast them all away
Among the clover-scented grass,
Among the newmown hay;
Among the husking of the corn
Where drowsy poppies nod,
Where ill thoughts die and good are born,
Out in the fields with God.
—Elizabeth Barrett Browning.

THE LAUGHALOT BOY.

The Laughalot boy is a gay little tad
Who lives in a gay little place
Where all the good people who meet him are glad
For just looking into his face.
And the birds that sing there from the dawn until night
Warble only such songs as give people delight—
Sing to add to the joy
Of the Laughalot boy,
Each with all of its glad little might.

Oh, the Laughalot boy always runs to obey,
And never is rude or unkind,
And only good people go smiling his way,
And woes never darken his mind;
The Laughalot boy is a gay little tad
Who has many more joys than the boys who are bad—
All the winds seem to go
As he wants them to blow,
And his laughing makes everything glad.

Concerning the Opposition

Confound the girl! Where on earth did she ever get such ideas? Have a cigar, Ted."

Theodore Lord lighted the proffered weed and smoked thoughtfully for several minutes.

"You have me there, Judge," he said at length. "Possibly from some of this latter day literature. It seems to me as if I had read something similar."

"Very possibly," said Judge Martin, frowning. "You say she thinks the affair too cut and dried?"

Lord smiled.

"She doesn't express herself in just those terms. She says everything is too obvious," said he.

Judge Martin snorted in disgust. "Too obvious! Too obvious! What in the world does she expect or want? I don't care if she is my daughter. Ted, I do think women folks nowadays get the wildest notions in their heads."

"She says," Lord continued, "it has been too glaringly apparent how everything would turn out. She can't remember the day, she claims, when it wasn't obvious that she would some day marry the nice little boy who lived across the street. She presumes, too, that it was just as obvious to the nice little boy that he would some day marry Judge Martin's daughter. Now, she says, it is obvious to everybody that we were made for each other. In fact, things have been so terribly obvious from the very beginning that she fears we don't know our own minds, and perhaps later we may find we have made a great mistake."

Judge Martin ran his fingers nervously through his bushy white hair.

"I always thought she was the most sensible girl in the world," said he.

"She is," said Lord quickly. "There may be reason in what she says."

"I know she thinks the world of you, no matter what she says," said the Judge stoutly.

"I've had the temerity to think that myself," said Lord, "and I've tried to think this state of mind is merely temporary with her."

He blew smoke rings thoughtfully.

"Perhaps if I went away this winter," he continued, "it might help matters. There's the trip to California, you know. I might take that."

"Nonsense!" the Judge exploded. "You can't leave your practice here. And you can't afford it, either. You'll need all your money for your house. The trouble is, Ted, this affair of yours has been altogether too smooth. It needs opposition to stir it into healthy life. I believe a little touch of romantic opposition would work wonders with Elizabeth."

"I'm inclined to think you're right," said Lord slowly.

The Judge brought his fist down on the library table with a bang.

"Confound it!" he said, his eyes twinkling. "I don't want you for a son-in-law. I've never thought of such a thing. Marry my daughter Elizabeth? Never, my presumptuous young friend. See the point, Teddy?"

Lord sprang to his feet.

"Judge," he said, "you're a thoroughbred.

The judge was evidently well pleased with himself.

"Somewhat better than California, I fancy," he drawled.

"Infinitely," the young man said with enthusiasm.

"Come around tomorrow at 3," said the Judge. "Elizabeth will be here then. Oh, I'll sit you beautifully. Take another cigar with you."

"Tomorrow at 3, then," said Lord, picking up his overcoat.

The Judge nodded and dropped one eyelid deliberately.

The following afternoon at 3 o'clock Theodore Lord and the Judge were again seated in the library. They looked nervously at each other, as conspirators have looked at each other for all time. They even grinned at each other a bit sheepishly.

"Hush!" said the Judge. "She will be coming down the stairs in a moment. When I speak loud you do it, too. There, that's her door now. She's coming." Then, with a sudden change of tone: "No, sir, I most assuredly do not propose to hand my daughter to you. It is the height of presumption to suppose that I would be willing to do any such thing. Never!" The Judge's voice quite shook with fury.

"I scarcely expected you to fly into a rage, sir, merely because I come to you and ask for your daughter's hand in honorable marriage."

"You didn't, eh?" The spasmodic anger of the Judge's voice was beautifully done.

"I confess I expected quite a different reception," said Lord.

"May I ask," said the Judge, hotly, "on what such expectation was based?"

"I thought you knew, sir," Lord said calmly, "of my honest affection for Elizabeth. I thought that would be very apparent, even to you. Indeed, your actions have led me to believe your consent would be freely given."

"Young man," sneered the Judge, "I like your nerve! Your supposition that I would give my consent for Elizabeth to marry a penniless young sawbones is quite on a par with your other mental process."

"I'll admit my practice and income are neither very amazing," said Lord with some heat, "but I think you'll find them sufficient to warrant the request I have made; besides which I have health and ambition and no intention to stagnate."

"Your practice and income, indeed; I like that. I've taken the trouble to find out a little about your practice and your income, which you're so free in alluding to, and all I have to say is that if you had as much of either of them as you have of amazing nerve you'd be the richest doctor in the county. But I prefer something a little better for my daughter than slow starvation. The upshot of the whole matter would be that you'd be coming home to me and I'd have to keep you both."

"What you say is insulting in the extreme," said Lord. "But I must remember that you are an old man and you are Elizabeth's father. Therefore I will pass your insults by. What I want to know is, Do you flatly refuse your consent?"

"How many times must I tell you so?" howled the Judge.

"Then it is only fair to you to say I shall try to win her affections without that consent," said Lord angrily.

"Do so, by all means," roared the Judge. "I can tell you now she doesn't care a snap of her fingers about you."

The portieres were flung violently apart and Elizabeth, white but with proudly lifted head and flashing eyes, stood before them.

"There you are mistaken," she said in a shaken voice, looking unflinchingly at her father.

For a moment there was silence; then the Judge turned to Lord.

"Leave the house," he bellowed.

"Father!" said Elizabeth.

"Leave the house before I throw you out," said the Judge.

Elizabeth walked over to Lord and put her hand in his.

"You may throw me out, too," she said quietly.

The Judge turned away, ostensibly to control his wrath.

"Keep the young idiot if you want him," he said, "I'm going to the club."

Late that evening Lord found the Judge in his favorite corner at the club. The Judge grinned as he came up.

"How about the opposition, eh? Have a cigar, Teddy."—Pittsburg Gazette.

A PERFECT LADY.

A little girl from a crowded tenement house was delightedly telling a friend in the College Settlement about her new teacher.

"She's a perfect lady, that's what she is," said the child.

"Huh! How do you know she's a perfect lady?" questioned her friend. "You've known her only two days."

"It's easy enough telling," was the indignant answer. "I know she's a perfect lady because she makes me feel polite all the time."—Selected.

He that follows nature is never out of his way. Nature is sometimes subdued, but seldom extinguished.—Bacon.

Work, work, work!
'Tis better to work than play—
'Tis better to do some little good
As we travel from day to day;
'Tis better to help some needy one
Than to idle our time away.

The best law—the golden rule.

Cookery Recipes

RECIPES.

Editor Cultivator: In a recent issue of the Cultivator I noticed a request for recipe for marshmallow cake filling and cucumber pickle, and I send "tried and not found wanting" recipes for both.

* * *

Cucumber Pickles.—Take only fresh, firm, unbruised cucumbers, wash carefully and pack in an earthen jar. We usually use a one or two gallon jar, because we only have a few vines. Put a handful of dairy salt to the gallon of "cukes" on top, then pour on boiling water until "cukes" are a little more than covered. Put on a saucer or small plate to hold fruit under, as any that stick out will soften. Let stand for 24 hours, then drain and recover with boiling water, Use no salt the second time and be sure to have water boiling hot as that is the secret. After another 24 hours, take fruit out and pack tightly into common one or two quart glass fruit jars. Have ready some boiling vinegar which may be spiced, if desired, and fill jar same as with fruit. Screw on cover and pickles will keep for one or two years.

* * *—

Marshmallow Cake Filling.—Put two tablespoons of good gelatin into one half cup of boiling water. When dissolved beat very stiff with two cups of powdered sugar. Flavor with vanilla or other flavoring as desired. Wet a shallow cake tin, same size as layers of cake, in cold water and spread mixture on smoothly and let stand over night. It is very easy to make and as most marshmallows that you buy are made of gelatin instead of gum arabic, you can have it just as good and know just what you are getting.—C. S., Fullerton.

Now, we assume the above is from a man. Besides the above initials, the name signed to the letter accompanying the above, was that of a man, and with no "Mrs." before it. In that case if he will come again we will be glad indeed to give the Cultivator sisters a little help, which will be appreciated, we feel sure. In fact Mr. "C. S." says: "I am not a professional cook, but I pride myself on being a good amateur and I am always looking for new dishes, and am always willing to give any body benefit of such small experience as I may have had. As I have tried several excellent recipes out of the Cultivator I thought I would try and get even."

Perhaps when the ladies see that the men are trying their recipes they will take more interest in this department and send in the "tried and not found wanting" ones. Come again, Mr. "C. S.", for while we know your recipes will not be "found wanting" the ladies will be—"found wanting"more of them. In fact it would be quite jolly if the men would post up and help out by cooking an occasional meal—say, a Sunday dinner. If this appeals to the "women folks," we'll take up a campaign of education and see if the men can be worked up to it. Usually, you know, the men are easily "worked," but whether we can fetch this can only be determined by trying. While waiting for the ladies to send in their wishes in the matter, we give below some crack-a-jacks on corn meal.

* * *

Indian Fruit Cake.—Take one-half cup of butter and one cup of brown sugar and moisten with half a pint of strong coffee; add one cup of New Orleans molasses, a teaspoon of allspice, one grated nutmeg and a teaspoon of powdered cinnamon, one well beaten egg and three cups of pastry flour sifted with a heaping teaspoon of baking powder and one cup of Indian meal. Beat steadily for ten minutes and then stir in a quarter of a pound of shredded citron, half a pound of large seeded raisins, cut in two, and one pound of currants. Turn into a round cake pan lined with greased paper and bake three-quarters of an hour in a slow oven. Ice while still warm with vanilla fondant frosting, decorating with tiny candied cherries and angelica cut in the form of small holly leaves.

* * *

Meal Timbales.—Two cups of corn meal cooked in slightly salted water for three-quarters of an hour, adding more water if necessary and boiling to the consistency of porridge. Pour into small timbale molds and set away to harden; when quite firm remove with a sharp spoon the center from each mold, leaving only a shell; unmold these, brush over with melted butter and crisp in a hot oven; then fill with any highly seasoned creamed or deviled preparation of meat, fish or game and serve inverted on a salpicon of mashed potato, garnished with sprigs of parsley and thinly sliced lemon.

* * *

Cornmeal Bannocks.—Take eight heaping tablespoons of meal and stir in two cups of boiling water; add four tablespoons of flour, a saltspoon of salt, one-fourth of a teaspoon of baking soda, two well beaten eggs and sufficient cold milk to form a thick batter. Beat for five minutes and drop in spoonfuls into hot fat, frying the bannocks to a golden brown. Serve with maple syrup.

* * *

Indian Griddlecakes.—Use boiling water to dissolve a teaspoon of baking soda, adding two cups of sour milk, a tablespoon of melted butter, a dash of grated nutmeg and a saltspoon of salt; then stir in equal parts of Indian meal and sifted graham flour, mixing until the batter is free from lumps. Have the griddle very hot and grease it lightly with a small piece of salt pork; pour the batter from a small pitcher in cakes of the desired size; when filled push the griddle to the back of the range, as the cakes should cook slowly.

* * *

Corn Gems.—Combine two cups of sweet milk, one well beaten egg, a pinch of salt, one tablespoon of brown sugar, a tablespoon of maple syrup, two tablespoons of melted butter, one cup of Indian meal and one cup of wheat flour sifted with a heaping teaspoon of baking powder. When very light stir in half a cup of finely chopped dates. Have ready hot gem pans, fill each about three-quarters full with the batter and bake thirty minutes in a moderate oven.

HEARD AT THE SEASIDE.

"As a high roller," remarked the wave boastfully, "you are not in it with me."

"For which you should be thankful," rejoined the beach.

"Because why?' queried the wave.

"Because," answered the beach, "you have me to fall back on when you go broke."—Chicago News.

HOMELY HINTS.

Cure for Burns and Scalds.—As burns and scalds are apt to occur at any time in any household it is necessary to keep on hand something with which to allay the pain and burning immediately and I would recommend (because knowing nothing better) an article which is always handy in almost every household, and that is a raw potato washed and peeled and grated. Apply the grated potato to the burn and bind it up. When that is dry apply more and I think you will agree with me that it is the handiest and quickest remedy as well as the most reliable cure.

* * *

To Purify the Sick-room Atmosphere.—Try burning eau-de-Cologne in a red-hot iron shovel when a sick-room becomes stuffy. It imparts a delightful fragrance which is very refreshing to the patient.

* * *

To clear the air of a room put a lump of camphor in a saucer and apply a very hot poker to it. This will cause very strong fumes which will cleanse the air speedily and act as a powerful disinfectant at the same time.

* * *

A hot water bath in which has been dissolved about two ounces of coarse salt, will cure tired, swollen feet.

* * *

The following recipe for cough medicine comes from a New England housewife, and was handed down to her from an old-time sea-captain: Blend one ounce of senna, one ounce of whole flaxseed, one ounce of crushed licorice and half an ounce of anise seed, and cook in boiling water (about three or four pints) until reduced to a quart. Strain, add one cupful of molasses and boil a few minutes longer. Then cool, and when cold add a little whisky or alcohol, to prevent fermentation. Keep the medicine in air-tight bottles. Use a teaspoonful or two when needed. This is effective for severe hacking colds and coughs.

THEY. DO THINGS DIFFERENTLY NOW.

Grandmama—When your grandpa was courting me he always kissed me upon the brow.

Granddaughter—If a man kissed me upon the brow I'd just call him down a little bit.—Smart Set.

THE TRAP DOOR SPIDER.

Interesting friends of ours entertainingly written about for Cultivator readers.

Since the trap-door or under-ground weavers are considered the most interesting of the hundreds of species of spiders, it is well for we Californians to have at least a speaking acquaintance with the ones living among us, and bearing our name.

While the Ctenize Californica is a distant relative of the dreaded turantula, let me say that this family and all other spiders have been grossly maligned. Some of the best authorities saying that no spider in this country is poisonous, and only in rare cases where the persons bitten is in peculiarly receptive condition, does any harm ever occur. Neither do they harm vegetation, but, rather, improve it by devouring myriads of injurious insects.

These little friends get their name from the fact that they have underground houses with doors that open and close, not back and forth like ours, but up and down. The trap-door is the front entrance and also the roof of the house.

I have been studying how to help you recognize this roof-door entrance when you see it, for it is not the intention of the big, hairy occupant that you should discover his abode. If you cut a "printing" D in the clay-like soil where they live and then walk over it until the cut is pretty well filled, it would look quite like the trap-door; that is, provided the straight part of the D is made a trifle shorter than usual.

The home of a full grown spider is about an inch in diameter, but these energetic little creatures do not wait until grown before going to live in houses of their own. Instead, they build small ones are soon as they are able to care for themselves, and enlarge them as they grow.

Having chosen a time when the earth is moist and a location where the soil hardens like clay when dry, the big black fellow begins to excavate a perfectly round hole straight downward, sometimes a foot deep, sometimes only two inches, and lines the walls of this circular room with a beautiful silken drapery called spider web.

Next the roof is made by spinning a web across the top of the hole and placing small particles of earth on it, then more web is spun, more earth used, and so on until this pad-like top is about a quarter of an inch thick. when the builder cuts it loose all 'round. except about one-third of the way, which is left fast for a hinge; and the round roof has now become the D-shaped trap-door.

In cutting the top loose it is beveled inward so that the door fits into the orifice almost as closely as a stopper into a bottle.

The hinge is a very wonderful part of these most wonderful houses. It is made tntirely of the web, and is warranted to wear as long as the owner lives. It holds the trap-door down so tight that you cannot open it from the outside without danger of breaking the edge.

Human carpenters cannot make doors fit and swing more perfectly than do these highly developed insects. —Mary Suydam Peck, Los Angeles. August 1, 1905.

KEEPING CIDER SWEET.

Sweet cider so preserved that it has exactly the same flavor and sweetness that it had the day it was made last fall is on hand at the Oregon agricultural college, at Corvallis. Samples recently tested demonstrate the plan to be entirely successful and render it certain that an industry in cider bottling is likely to be the consequence. The method of treatment of the cider is to destroy the ferment germ by a temperature so low that it will not cook the apple fiber that may be in solution and also not destroy the natural flavor. For the purpose, a temperature of 160 degrees, secured by steam process, is applied. This is sufficient to destroy the vegetable cell, but not enough to kill the spores. Accordingly, twenty-four hours later, when the spores have developed into cells, the same heat is then applied. Twenty-four hours later, as a precaution, a third application of heat is made. Then the cider is corked up in bottles tightly enough to prevent the air from coming in contact, and the bottles are laid away. Such bottles opened recently contained cider as sweet and wholesome as ever came from a press. The feature of the process is that by reason of the simple method of treatment, anybody can preserve the beverage for future use at a very trifling expense.—N. W. Horticulturist.

BREAKING A HABIT.

How shall I a habit break?
As you did that habit make.
As you gathered you must lose;
As you yielded, now refuse.

Thread by thread, the strands we twist
Till they bind us neck and wrist;
Thread by thread, the patient hand
Must entwine ere free we stand.

As we builded, stone by stone,
We must toil, unhelped, alone,
Till the wall is overthrown.

PERFECTLY CLEAR.

Visiting Tourist (to rural inhabitant)—"Are you a native of this place?"

Inhabitant—"Am I a what?"

Tourist—"Are you a native?"

Inhabitant's wife (appearing on the scene)—"Ain't ye got no sense, Rube? He means, wuz ye livin' here when ye wuz born, or wuz ye born before ye began livin' here?"—Harper's Weekly.

The best education—self-knowledge.

Corn ..... 1.35@1.40

Selling prices of mill stuffs f. o. b. cars L. A., in quantity, are:

Rolled Barley 1.10
Bran $1.20
Feed Corn Meal $1.60
Middlings $1.35
Cracked Corn $1.55
Corn $1.50
Oil Cake Meal $2.10
Cocoanut Meal 1.55

San Francisco Markets.

San Francisco, August 9, 1905.

DAIRY.

Butter is none too plentiful in the market and rules very firm, choice stock commanding top quotations. Some sales are even reported one-half to one cent in advance of quotations. Cheaper sorts of butter are in more liberal supply, with some difficulty in getting full quotations.

BUTTER—Per lb:

Creamery, fancy 24	
Creamery, good to choice .22	@23
Dairy, choice 20	@21
Store 17	@18

CHEESE—Per lb:

Cal. Creamery, mild new, ex.11	
Do, choice 9	@10
Young American 12	@13
Eastern, N. Y., Cream 17	@18

EGGS.

Eggs are much firmer, top quotations being the rule with offerings very moderate. Cheaper grades are more plentiful, with sales slower.

EGGS—Per doz:

Ranch, selected large 31	@32
Ranch, good to fancy 27½	@30
Store 18	@23
Eastern, extra 23	@24
Eastern, firsts 19	@21
Eastern, seconds 17	@18

POULTRY.

Poultry is arriving quite freely from local points, though prices are maintained, turkeys commanding one to two cents above quotations.

POULTRY—Old Roosters, per doz., $4.50@5.00; young Roosters, $4.50@6; Fryers, $3@4.00; Broilers, $2@2.50; Hens, small, $4@5; large, $5.50@6; Live Turkeys, per lb., 18@20c; Spring Turkeys, 23@25c; Ducks, old, $3.50@4; young, $4@4.50; Geese, per pair, $1.50; Goslings, $1.50@1.75; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $1.50@1.75.

FRESH FRUITS.

Apples, per box, fancy, 85c@$1.25; common to choice, 40@75c; Crab Apples, per box, 75c@$1.75.

Figs—Per box, Black, $1@1.50, as to size of package; White, 75c@$1.

Pears—Per box, Bartlett, 75c@$1.50; bulk, per ton, nominal; other varieties, per box, 50c@$1.

Peaches—Per box, 35@50c; carriers 50@75c; open boxes, 30@75c; bulk, per ton, nominal.

Plums and Prunes—Per small box or crate, 50@85c, as to variety; open boxes, 35c@$1; bulk, per ton, nominal.

Nectarines—Per crate or box, 50@85c.

Quinces—Per box, 65@85c.

Grapes—Per box or crate, Seedless, 85c@$1; Fountainbleau and Sweetwater, 60@85c; Muscats, 75c@$1.25; Blacks, 75c@$1.

Cantaloupes—Per crate, River, 75c@$1.50; Watermelons, per doz., $1@3; Nutmeg Melons, 35@75c.

Blackberries—Per chest, $1.50@3.

Raspberries—Per chest, $6@9.

Strawberries—Per chest, Longworths, $4@6; large varieties, $2.50@$5.

Huckleberries—Per lb., 7@8c.

VEGETABLES.

VEGETABLES—Tomatoes, per box, 25@40c; Green Peppers, per box, Chile, 65c@$1; do, Bell, 85c@$1.25; Okra, per box, 75c@$1; Garden Beans, per lb., Green, 6@7c; do, Wax, 6@7c; Lima, 6@8c; Garden Peas, per lb., 3

@4c; Cucumbers, per box, 25@40c; Summer Squash, per box, 25@40c; Egg Plant, per box, $1@1.25; Garlic, per lb., 4@5c; Green Corn, per sk, $1@1.75; per crate, $1.50@2.25.

POTATOES—Per ctl: River Burbanks, 40@65c; Salinas Burbanks, 85c @$1; Early Rose, nominal; Garnet Chile, 40@50c; Sweet Potatoes, per lb., 2@3c.

ONIONS—Per sk., Yellow, 75c@$1

DRIED FRUITS.

There is the keenest of interest in the dried fruit market, prunes especially holding foremost place. Growers are very strong in their demands. Peaches are also in high favor and spot cash sales are already being made.

DRIED FRUITS—Prices for carload lots, f. o. b., at California common shipping points, in bags, are, per lb., as follows:

Peaches—1905 crop—Crawford, fancy, 7@8c; choice, 6¾@7¼c; standard, 6½@6¾c; Muirs, fancy, 8¼@8½c; choice, 7@7¾c; standard, 6½@6¾c.

Prunes, 1905 crop—Sack basis, f. o. b.: For boxed goods add ¼@½c; 3½@3¾c basis for Santa Clara; other sections ¼c less; old crop, 2¾@3c.

Apricots, 1905 crop—Royal, fancy, 7¾@8c; choice, 6¼@7c; standard, 5¾@6c; Moorpark, nominal.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c, choice, 3¼c; standard, 2¾c; ungraded, 3½c.

HONEY AND BEESWAX.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

HOPS.

The price of desirable stock is nominal at 24@27½c per lb, according to quality, many producers demanding thirty cents.

BEANS AND SEEDS.

BEANS—Prices per ctl. for sound selections; Large White, $2.75@2.90; small do, $3.50@3.75; Pea, $3.25; Limas, $5.50@5.75; Red, $6.50@8; Pink, fancy, $3.65@3.90; recleaned, ordinary to choice, $2@2.50; Bayos, $4@4.50; Blackeyes, $3@3.25; Red Kidneys, $4@4.50; Rain damaged lots of all descriptions offering from 50c@$2 a ctl below foregoing figures, according to condition.

LIVE STOCK.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@5½c; rough heavy, 4¼@4½c; common, 3½@4c.

HAY AND FEEDSTUFFS.

HAY—Per ton: Wheat, $9@13.50; Wheat and Oat, $8.50@12.50; Oat, $7.50@11.50; Barley, $7@9; Clover, $7@10; Alfalfa, $6@10; Stock, $5.50@7.50.

New crop Wheat, $9@13.50; Oat, $5.50@11; Wheat and Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $21.50 @22.50.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@28.50.

FLOUR AND CEREALS.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70 @4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.35@$1.42½ for new crop; old higher; White Milling, good to choice, $1.45@1.55 for new and $1.60@1.65 for old.

BARLEY—Choice, No. 1 Feed, $1@1.05; some fancy up to $1.06¼; off grades, 97½@98¾c; Shipping and Brewing, $1.05@1.10; Chevalier, $1.10 @1.25.

OATS—Good to choice, White nominal; Red, $1.17½@1.35 for new crop; Black, nominal.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.40@1.45; small do, $1.55@1.62½; White, $1.37½ @1.42½; Eastern, Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.40.

RYE—Good to choice, per ctl., nominal; new, $1.47½@1.50.

CITRUS MARKETS

The few oranges now going forward are commanding record breaking prices. Even the auctions are commanding $1800 to $2000 per car. Valencias are practically the entire offering, though a few Sweets have been forwarded during the week. The Valencias are found to be excellent keepers and are in strong demand with retailers. It is questioned, however, as to capacity of market to absorb large offerings at this period of the year.

Lemons maintain a strong market, affected, in part, by the close, warm weather. Prices of $3 to $6.50 have been commanded by every offering. Nearly all foreigns are picked up at eastern points, and even there have not depressed prices The California lemon is a strong favorite over the imported in many markets.

NEW YORK.

Last week's orange sales showed the highest prices of any week during the entire citrus season. The coming week, or this present week, rather, promises a much larger showing than that. There was an exceedingly small supply of fruit in the market, quickly picked up at top quotations. California deciduous fruits are not as plentiful as heretofore which may have something to do with the exceedingly high prices which are obtaining in the citrus market. Eastern grown fruit, and especially peaches, will soon be much scarcer; in fact, are now limited, apples and pears being the principal deciduous fruits.

Monday's sale took four cars, principally Valencias. Market was very strong. Weather favorable. Fancy Valencias brought from 4.70 to 6.30 while choice sold at 4.25 to 4.35. Grape fruit was exceptionally strong, extra choice California selling at 5.40. California lemons very strong, holding close to the 5.00 mark.

At Tuesday's auction five cars were sold. Market remaining strong, especially on first-class fruit. Weather pleasant. Valencias, fancys, brought 5.00 to 6.20, choice, 4.00 to 5.50. A few sweets sold close to 4.00; lemons maintaining the 5.00 mark. At Tuesday's sale, the banner sale of the season was on a $2082.80 car, being of Old Mission Valencias. Demand for Valencias is almost phenomenal this year.

At Wednesday's auction there were only two cars offered, one of Valencias and the other of lemons. Prices of both maintained high average with no prospect of decline. The highest grade Valencias commanded an average of $6.20 per box, extra choice bringing about $4.50. Lemons held close to the $5 mark.

There were 20,000 boxes of Sicily lemons of good stock, which commanded high prices.

BOSTON.

Only one car offered on Monday, fancy Valencias, and brought close to $5.00 a box. Market steady. Weather very hot.

Also on Tuesday one car. These were choice Valencias, and realized almost as much as the fancys of the day prior. Market steady and light quantities being offered.

One car Valencias, one car lemons sold on Wednesday. Weather hot and close. Market firm. Valencias brought from $4 to $4.50; lemons close to the $5.25 mark.

PHILADELPHIA.

Four cars sold on Monday. Market generally steady with a very strong advance on lemons. Fancy Valencias ranged at about 4.15 while some choice brought from 3.75 to 4.00. Lemons sold at 5.50 to 6.00.

Wednesday's sale consisted entirely of lemons, two cars being offered, standards bringing $4 and above, while extra choice, showing considerable decay, brought about the same price.

* * *

CITRUS SHIPMENTS.

Total shipments since November 1, 28,464, of which 2635 were lemons.

IRRIGATION A NATIONAL BENEFIT

There is no longer any issue as to the question of irrigation. It is universally admitted that there is no more imperative duty on the part of the government than that of reclaiming, for the benefit of all the people, those portions of the public domain which are arid and at this time unfit for cultivation. That is now being done and in a way that insures the best possible results not only for the regions immediately interested, but as well for the country at large. In other words the progress of irrigation means benefit for the whole country.—Bee, Omaha, Neb.

HOW TO KEEP COMB HONEY.

The graulating of honey in the comb makes it more unsalable than almost anything else that can happen to it which does not destroy the comb. Owing to this, comb honey should always be kept in a warm, dry place. It may be stored through the winter in a dry basement room or cellar, provided no frost reaches those apartments; but if there is a sudden rise of temperature outside much above that inside, moisture is liable to gather and stand in drops on the combs, in which case the honey will rapidly deterioriate. The only sure way of preserving comb honey so that it will present a salable form, is to store it in rooms so constructed that the temperature there will remain between seventy and ninety degrees and never go below sixty degrees.

When your butter-maker insists that the cream be delivered in good condition, he is doing the right thing, it is more to the benefit of the farmer than any one else, his requests should be heeded and promptly complied with. Sour cream does not test as well as sweet cream, the product made from very sour cream turns rancid much quicker than when it has the proper acidity, and causes the butter to sell at reduced prices.

IN WOMAN'S BREAST

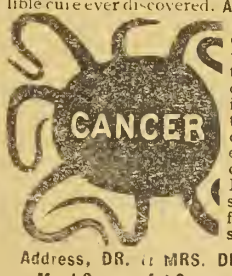
ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

THREE PHYSICIANS OFFER $1000

If They Fail to Cure Any Cancer

Without KNIFE or PAIN AT HALF PRICE for 30 days. Not a dollar need be paid until cured. Only infallible cure ever discovered. ABSOLUTE GUARANTEE.



Best book on cancers ever printed, sent FREE with testimonials of thousands cured without a failure. A Pacific island plant makes the cures. Most wonderful discovery on earth. Small cancers cured at your home. No X-Ray or other swindle. Write today for our 130-page book, sent free.

LOS ANGELES SAN FRANCISCO

AUGUST 18, 1905

WHERE ALFALFA PRODUCES FROM THREE TO NINE CROPS A YEAR.

The comparatively new forage crop, in the United States, alfalfa, is probably at its best in portions of California. Where soil conditions are right and where plenty of water for irrigation can be obtained, the crops are astonishing. Alfalfa, irrigation and high-grade dairy cows are particularly profitable in Southern California, and in the great San Joaquin valley they are causing the vast wheat fields to be cut up into small farms for the large number of settlers coming from the East.

CIRCULATION EXCEEDING 10,500

THE MAKING of a SUCCESSFUL POULTRY FEED

Part view of the manufacturing department where Coulson's Egg Food and Coulson's Chick Food are made. Notice solid stone floor. See the men at work bringing the different feeds and ingredients to the mixing machine. Thousands of sacks are handled daily. There is one pile containing over a thousand sacks of Armour's Meat Meal. Another pile of sacks of fine ground Bone Meal. Another pile of three thousand sacks of shorts. Another of fifteen hundred sacks of flour middlings. In another place you will notice a carload of Armour's Dried Blood. In another, eight hundred sacks of fine ground beef scraps. In another pile a carload of ground oats, and in another a stack of two cars of granulated corn meal, and back in the corner sixty thousand pounds of Minnesota Millet Seed, car lots of Cracked Rice, steel cut Oat Meal, different seeds, etc. There are tons of charred bone Charcoal, and barrels of powdered Willow Charcoal, and big stacks of many other ingredients.

OUR SPECIALTY—MAKING GOOD FEED.

John D. Rockefeller's specialty is oil, Andrew Carnegie's, steel; Senator Clark's mining. These men were and are specialists. They organized themselves to excel, just as we have organized ourselves to excel in the manufacture of the BEST FEED for POULTRY. It is the one thing we think of, dream of, and talk of. When a man's heart is set on his task, he does it better than the "don't care fellow."

We do not and will not employ any one who is not interested in their work, consequently we repeat to you that we make GOOD FEED FOR POULTRY, (none better but lots that are worse, we assure you.) Making GOOD FEED for poultry is our specialty, and we have got it down to perfection. We manufacture a feed that will make your hens lay, as you never dreamed of before. Not only is the feed good to make hens lay, but it helps the fowls and it also gives them richer blood and keeps them in healthier conditions.

Being specialists in the line of mixed poultry feed, we can give you the best feed at the lowest prices.

All fowls over two months old, pullets and laying hens should have one meal a day of Coulson's Egg Food as a warm mash. Feed it for one year and see what there is in it.

It takes several weeks to show any great gain in egg production on any change of feed. Many poultrymen have tried Coulson's Egg Food for a while there are hundreds and even few days and given it up as a failure, thousands of poultry keepers who have fed Coulson's Egg Food for over a year's time and have made the greatest of success, and who feed Coulson's Egg Food every day to their hens, and every day they get plenty of eggs.

TWO HUNDRED HORSE-POWER ENGINE.

That runs the machinery which grinds up the bones for making fine ground bone meal, and pulverizes the charred bones for making Bone Charcoal. Etc.

These ingredients are used in making Coulson's Egg Food (a mixed food for pullets and laying hens) and Coulson's Chick Food, which are mixed by machinery and mixed properly.

The healthiest looking fowls, with bright red combs, are those that are fed on Coulson's Egg Food.

TRY IT FOR ONE YEAR.

Experience, backed by the general law of average, proves that feeding any change of food for the first week or two doesn't bring results. A trial of a SACK OR TWO is a waste of money. If you GO IN, stay in, and it WILL PAY YOU. "Keeping everlastingly at it" is the ONLY WAY TO SUCCESS.

MR. POULTRYMAN, there is only one way to buy, and that is on record of WHAT YOU WANT. If you want to make a good record, buy good feed. Character is a man's record. So it is with feed. Buy on character. When you buy Coulson's poultry foods you buy on character, and get a standard article of feed that contains only the best and wholesome ingredients.

Rumsey, Cal., Dec. 15, 1904.

This is the first season I have used Coulson's Egg Food and I find it excellent for the purpose. Since feeding it I have had more than double the number of eggs that I ever have had before from the same number of hens.

Yours truly,

A. A. HENRY, Rumsey, Cal.

Hints on Home Manufacture of Olive Oil

While Home Extraction is Not Recommended, Yet Under Proper Conditions and Absolute Purity, It May Prove Successful

As was noted in last week's Cultivator, request is in hand for information regarding the home manufacture of olive oil, the inquirer having supply of olives, too far from any olive mill and being unable to consume all the product put up as pickles. This is a matter which would be hard to treat, at least to the extent of giving explicit instructions as to each detail of the work. Manufacture of a good grade of olive oil is one requiring some considerable machinery and is a process of many details, covering quite a period of time. However, it has been done in a small way and where the grower of the olive goes into it with determination and gets some little practical information in advance, he may succeed in making a good grade of oil. As the creamery has largely taken the market from the dairyman and enabled a higher price and a more regular price to be commanded for butter, so the manufacture of olive oil requires a degree of expense and completeness of outfit which the small manufacturer can not always command. However, for home use, or possibly for select customers where one may be able to guarantee absolute purity of the article and secure a good price for his output, it may possibly prove attractive to make, in a small way, a good grade of olive oil.

The State Horticultural Commission has issued one bulletin which gives quite an extended description of method of manufacturing oil, as has also the State University, which has issued several bulletins. These give much more explicit information than is possible in a short article of this kind and the most we can do will be to give a few general hints.

Of course, still better than any outline of the process which we can give and the perusal of the bulletins recommended will be a personal inspection of some small mill. There are some small mills constructed for use in limited manufacture, also presses. In fact, some oil manufacturers have devised their own crude and, at the same time, fairly effective presses for pressing the oil and water from the pulp. But unless one has considerable ingenuity, of course this would not prove very attractive. We give on this page illustrations of effective mill and press built on small scale.

The crushing in a commercial way is usually accomplished by two large steel rollers rolling around in a steel pan, crushing either the pulp from the stones or crushing pulp and stones together. Some manufacturers prefer the oil which comes from the pulp only, claiming that the pit has an exceedingly small content of oil which gives a lower grade of oil, much more liable to turn rancid. This is disputed by others, however, and it may be said that the highest honors at the St. Louis exposition were taken by an oil made from both crushed pits and pulp. So we do not think it a material point as to whether you provide means for crushing both pulp and stones or removing the stones and crushing the pulp only.

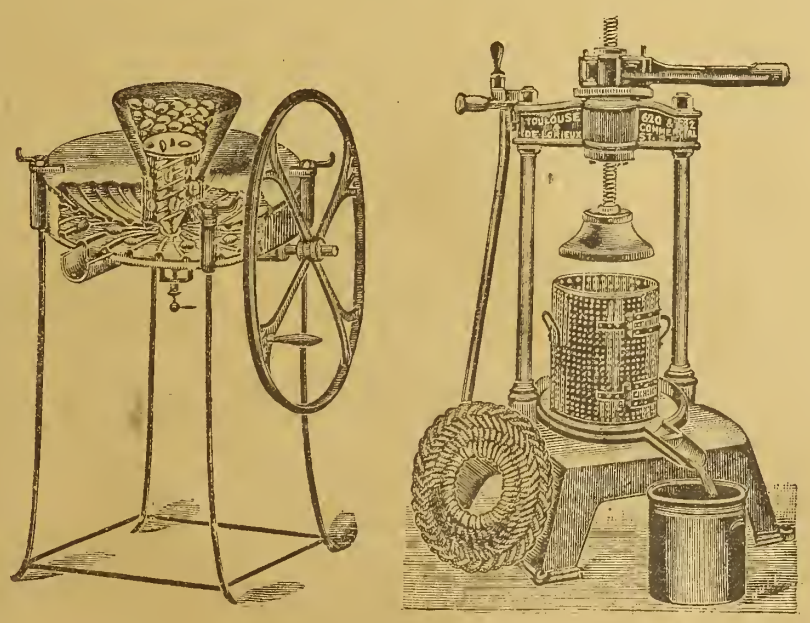
From the crusher, the pulp is taken directly to the press where various appliances, such as grass mats or bags and perforated plates to hold the pulp while the pressure is being applied are usually used. The pressure from the screw, or hydraulic press, as the case may be, should be very gradually increased, some going to the extent of separating the very first pressing from the later pressing, claiming it produces much the finer oil. However, usually the entire amount is pressed from the pulp or at least as much as possible. Sometimes the pulp is retreated and pressed a second and even the third time. These, however, produce an inferior oil. From the press the liquid, which consists of the fruit juices mixed with oil and particles of pulp, is placed in the receiver where it is allowed to remain a few days, when the oil, like cream rising on the milk, rises to the surface, leaving the sediment and water underneath. This oil is further purified and clarified by filtration through either the regular circular filtering paper or through absorbent cotton. Regarding the matter of filtration, we may quote from Bulletin No. 158 of the University Experiment station, to which we have referred.

"It is not at all essential to filter oil in order to obtain a perfectly clear and bright product. The writer has seen unfiltered California olive oil which had been bottled ten years and was still as bright as when first put up. The essential element in obtaining such oil is time in which to obtain a perfect racking. If sufficient time is not allowed a sediment will certainly settle in the bottle, which will as certainly spoil the market value of the oil. While the separation of this sediment, or the separation of the solid fats, is not a sign of an impure oil, yet either is fatal to the market qualities of the oil."

The one great essential in the entire process may be said to be absolute cleanliness, and protection of the oil from any odors or from any contamination which will affect its flavor and, still more, its keeping qualities.

The condition in which the fruit should be when it is picked is a question of some little difference of opinion. It should, of course, have lost its green color and turned the purplish or dark shade but as a rule manufacturers prefer that it should not completely ripen, or at least wilt on the tree. Notwithstanding this, we have seen mills using olives which were picked from the trees as late as February which had passed through some quite severe weather, frost having wilted the fruit very generally and it is claimed that oil from this fruit was of almost as good flavor as that made from the earlier picking in the fall. Most manufacturers prefer the partial drying of the fruit after it is picked from the trees, leaving on trays for several days, thus compelling loss of much of the moisture, consequently slightly more economical handling. But others claim finer grade of oil can be made with fresh fruit direct from the trees. In any case the fruit must not be allowed to mould or taint in the least, or the best grade of oil cannot be the result.

One great trouble with the manufacture of olive oil in this country is the great cost of manufacture, for, as it is claimed, unless the grower can receive at least $20 per ton over and above the cost of picking, he can not continue to grow the fruit. At that price, with the manufacturer compelled to make quite extensive investments in machinery and appliances, there is almost no profit where he has to compete with the prices at which the importers sell their oil. However, as we noted, it is to be regreted, for this country imports nearly two and a half million dollars worth or oil, annually, while California produces slightly above $150,000 worth so that it is plain the field is here if by some means of central mills or cheaper methods, the manufacture can be so cheapened as to place the oil in market in competition with that of European manufacture. The question of quality has never been raised for in that respect California has competed with the world and almost invariably proved the winner.



OLIVE CRUSHER AND PRESS
For small or Home Manufacture of Olive Oil

Forty thousand dollars is to be expended within the next three months in protecting the banks of the Eel river from the floods of winter. The work will be paid for from funds voted by the last legislature and private donations of Eel river farmers and dairymen.

California Horticulturally

By John Isaac, Sacramento, Cal.

"ANTIS" AS CHECKS FOR DISEASES.

A Stockton horticulturist, in an interview in the Mail of that city, advances the theory that all pests and diseases in the vegetable world can be counteracted by what he describes as "antis." Or, in other words, by their opposites or enemies. There is no question as to the correctness of this theory, and it is upon it that the State Board of Horticulture has operated so many years and with such marked success. Its operations have been confined to finding the "antis" in the insect world and they have been found to such an extent that we have very few serious insect pests which have not their natural enemy to keep them in check. The one great law of the natural world is that no species shall become redundant. If it did, it would soon crowd all others off the earth, and retrogression, decay and death would follow. So, in order that we may progress, we have to meet and overcome our opposites, and life from the lowest to the highest becomes a continuous struggle. This is equally true of the vegetable world. Now, when any species is introduced into a new locality without its natural enemy, or check, there is great danger to be apprehended from it, and this danger will continue until its natural check has been introduced, or some other adapts its taste to it. This we know is true of insects, and it is unquestionably true of such diseases as the pear blight, walnut blight, and others, which we know as bacterial diseases. Much attention has been devoted by scientists to discovering checks for bacterial diseases of mankind, and in many cases their checks, or "antis," as this correspondent terms them, have been discovered. Now, on this theory, it is easy enough to check any of the more serious of our tree diseases; all that we have to do is to discover their "antis;" that's all.

* * *

SILK CULTURE IN SYRIA.

We have lately received from a gentleman in Syria a letter in regard to silk culture in that country, and as much attention is now being paid to this industry in our State, a comparison of conditions between it and Syria, where sericulture has been the chief industry for ages, may be of interest:

"Syria and California are very much alike in the matter of climate and agricultural and horticultural products. Our chief productions are the olive, the mulberry and the grape. Our methods of cultivation are different to those of California. We graft our trees as you do, but generally prefer budding. At the present time the chief products o fthis country are olives and silk. Mulberry trees are very abundant, especially in this district (Ebil, Syria), and Mount Lebanon. I desire in writing this letter to get some information in regard to California methods in raising silk worms, as the process here is a very tedious one, taking very much time and requiring a great deal of labor, while the whole harvest of cocoons is often lost either from neglect or disease, or worms of poor quality are produced.

The Syrian people, especially the more wealthy classes, pay a great deal of attention to the cultivation of the mulberry, and a great many new orchards have been planted in irrigated lands. Owing to this, there has been a greatly increased output of mulberry leaves and prices have materially declined and silk cocoons have also been declining for the same cause.

There are several varieties of mulberry trees in this country, the most popular of which are comprised in six varieties, three of them fertile trees, bearing white, red and black berries. The other three are grown wholly for their leaves, which are used for feeding the worms. The leaves of these trees are very large and thick.

Mulberry trees attain a great age in this country, especially in the vicinity of Aleppo. The fruit in many sections is very sweet and is used by the natives for drying."

* * *

TREES IN THE CAPITOL PARK.

Miss Alice Eastwood, botanist for the Academy of Sciences, has now completed the work of classifying, naming and labeling the trees in the Capitol Park at Sacramento, a greatly needed work well done. There are here over two hundred different species, very many foreign varieties and many of them of tropical nativity. These trees, many of them strange, have been a great attraction to the grounds, especially to visitors, who naturally were curious to know their names, sections in which they originated. All are now labeled, the labels giving the common names, the scientific names and country of origin. We question whether, in the same space anywhere, there can be found so great variety of vegetation as on these grounds. Here, growing side by side, are the pines of the north and the palms of the south, the magnolia and the cedar trees from the north and the south, those which flourish in the high altitudes and those native to the low, trees of the arid and the humid regions and, strange to say, all do well. It would seem that here all the vegetation of the world can meet on common ground, on neutral ground as it were, and all do equally well. The trees of the capitol grounds form one of the features of the capital city and of the State, and in naming them so that strangers and the uninformed can recognize them and know them at a glance, the Capitol Commissioners, aided by Miss Eastwood, have done a very creditable piece of work.

* * *

CALIFORNIA FREE FROM INSECT PESTS.

Somehow or other there is always a vast amount of consolation for us in trouble if we only see some one else worse off than we. That is why I wish to call attention to the fact that there are others who are suffering more from insect pests than we of California. In California we sometimes have an outbreak of grasshoppers, as we have had this year, which do some damage, then the red scale in our orange orchards, which requires some labor and expense to keep in check, sometimes there is a slight outbreak of army worms and other pests, in small numbers or in limited areas, are reported, but none of these can compare in destructive work with that wrought by a single species in some parts of the East. Consider the Gypsy moth in Massachusetts, for instance, which has cost that State already over half a million and it has the pest yet. Then there is the cotton boll weevil of the cotton States, which has in some sections rendered cotton growing impractical and forced its abandonment. Then there are the plum curculio and the plum gouger, with neither of which we are acquainted. Then there is the chinch bug, the Hessian fly, both infinitely worse in the eastern grain fields than in those of California. Then there is the San Jose scale, sent to the East from California, and which, no longer a pest here, has developed to one of the most terribly and costly scourges which the eastern orchardist has ever been called upon to face. Here we have pear blight, there they have it too, and in addition peach yellows, peach rosette and littles. And so we might continue almost without limit, but enough has been said to show that our pests are not so bad after all. The Department of Agriculture has issued statistics showing that insect pests cost this country $785,000,000 a year, and it is certain that they are not all in California.

* * *

CULL FRUIT FOR THE HOME MARKET.

San Francisco and other California towns every year register a just complaint over the fact that, while the markets of the East are supplied with the choicest of California fruits, the culls are dumped in our local markets, and California consumers are supposed to eat what the eastern consumer would reject. There is altogether too much truth in these complaints and good grounds for them. It is a fact, that the poorest fruit grown in the State finds its way to our home markets, and this is especially noticeable the present year. There is a great shortage in most of the fresh fruit crops, accompanied by a good demand. As a result, growers and shippers are carefully selecting fruit for the eastern market, while stuff that would disgrace any producing section is dumped on the home market. It is almost impossible to purchase at any of our fruit stalls peaches which are not deformed, half ripe and full of worms, apricots are a solid mass of scab from shot-hole fungus, while pears and apples are cracked and blotched with scab. It is true that the fruit crop this season is not up to standard, but in spite of that fact, the California consumer should receive the same consideration which is given the eastern er, for surely his money is as good, and generally he pays as much for what he gets.

"I take notice," said Uncle Eben, "dat de man who tells you how easy it is to be contented wif salt po'k an' beans giner'ly has as fine a appetite foh fried chicken as anybody."—Washington Star.

SLAVES OF THE ANT.

Prof. Cook once wrote in this department that certain insects, especially the ant, make subjects of other insects and compels their services in supporting the ants. Particularly did he speak of the fact that certain ants would enslave certain aphis, using them for food supply as the humans maintain a dairy.

An advance bulletin from Illinois State University now shows that this trait of ants has become an embarrassing problem before the Illinois corn grower. In speaking before the summer session of the State University recently, Prof. Stephen A. Forbes, State Entomologist, gave the life history of the corn root aphis. From this bulletin we note:

"This aphis, one of the many species of plant louse, seems to be growing yearly more destructive, and is seriously threatening the corn crop in many parts of the State and country at large. Where this insect abounds, the crop is injured sometimes to the extent of fifty per cent, and the farmers are beginning to complain more and more about its ravages.

Until recently, little was known about the nature and habits of this pest, but Professor Forbes and his assistants have learned much about its life history and the best methods of preventing its ravages. The aphis is itself, completely helpless. If left to itself, it could not procure food, so slight is its intelligence.

The brown ant, however, which gets its living from the juices secreted by the aphis, sees to it that this little animal gets sufficient food. It is an interesting fact that this aphis could not exist without the ant, and the ant itself, during a large period of its life, would die of starvation without the aphis. So these insects have formed a co-operative society, in which the aphis looks out for the food supply, and the ant gives the necessary direction by means of its superior intelligence.

This variety of aphis, as its name indicates, lives on the root of the corn plant. The ant digs a tunnel from the surface of the corn hill down to the root, and then carries the aphides down this underground passage, and deposits them where they will get the most nourishment. The ants do all the selecting, and if they do not consider the place they first choose as satisfactory, they remove the aphides to a more favorable locality. The aphides themselves seem to be entirely neutral in the matter. Their business is to eat abundantly.

The aphides act upon the corn somewhat in the manner of a drought. They deprive it of its juices, and it starves to death. The prevention of this pest has become an economic necessity, and it can be entirely eliminated by destroying the ants who keep it alive."

The treatment which the bulletin recommends is thorough cultivation and rotation of crops.

THE RELATION OF INSECTS TO HEALTH.

During the course of the lectures before the summer school of Illinois University, Professor Forbes discussed the question of the relation of various insects to the health of a community. He explained the manner in which certain varieties of mosquitoes carry the germs of malaria and yellow fever, and stated that if these insects could be removed, these two diseases would be unknown. He also showed the part that the common house fly plays in the spread of typhoid fever by visiting sink drains, and other infected places, and by subsequently lighting on food. Fly-paper and screens are of great value from the standpoint of public health.

Dr. Forbes emphasized the fact that the activity of flies in the retention camps in the southern part of the United States during the Spanish American war, was responsible for more deaths than were the Spanish bullets. In later lectures in the series Professor Forbes considered particularly the great value of bird life to the farmer, and the fruit grower, in keeping down the scourge of insects, and urged that the community should acquaint themselves with the laws for the protection of birds and see that these were enforced.

RESTRICTING SHIPMENTS OF INFECTED FRUIT.

A meeting of the Santa Barbara County Horticultural commission was held at Lompoc, last week, C. J. Russell of Santa Maria, and W. H. Schuyler of Lompoc, the other members attending. Dr. Yates, one of the members, gives the following account of the session:

Mr. Schuyler reported his action in regard to the resolution passed at the last meeting in relation to the prevention or regulation of the shipment or removal of infested fruits from the orchards where grown. He also moved that, as infested fruit has been, and is still being sold and shipped out of the district, that the secretary be instructed to confer with the State Horticultural Commissioner as to the best method to prevent such shipments or removals and also to ask that the individual members of this commission be appointed as deputy inspectors under the State Commission.

The commission further requests that the Southern Pacific railroad company will so instruct its agents that they will not ship fruits, trees or vines from any of their freight depots to any other point outside of the horticultural district in which said fruit is grown without a certificate from the horticultural commissioner of the district that the fruits or trees are free from any destructive disease or pests, which may be a menace to the locality to which the said fruit or trees may be addressed.

Mr. Schuyler reported that on a recent visit to Santa Cruz island he had found the black scale, and he had also found that the scutellista had been working the destruction of the scale.

Mr. Russell reported that infested apples were being shipped in from San Luis Obispo county to Santa Maria, and the board advised him to stop all such shipments of apples infested with the codling moth, when found to be so infested.

The board were also of the unanimous opinion that stringent methods must be adopted to prevent the spread of the "San Jose scale," and other injurious insects now infesting the Lompoc valley and adjacent country, as, unless this is done, the apple industry of the region will be entirely destroyed.

"RED LEAF DISEASE."

The mysterious "red leaf disease," which was first observed in the vineyards of Sonoma county two years ago, and which was at once given attention by the viticultural experts at the State University, forms the subject of a bulletin recently issued by the agricultural department of the university, the author being Ormond Butler, who was delegated to investigate the disease.

While investigating the "red leaf disease," Mr. Butler found that a number of maladies, either parasitic or physiological, were responsible in a measure for the weakness or dying of the vines. Among these affections, phylloxera, root rot, mildew, lack of affinity between scion and stock, lack of adaptation of stock to soil, mechanical injuries, erinose and black knot are quite prevalent in Sonoma county, as well as in most vineyard districts of California.

Mr. Butler's observations seem to show that the cause of the red leaf disease is not parasitic, but that it is probably due to soil and atmospheric conditions. These observations will be kept up during the coming season, and a careful examination of the sub-soil and moisture contents of the experimental plots will be made through the growing season, so that definite conclusions may be drawn.

THE MOST VALUABLE PIECE OF REAL ESTATE IN THE WORLD.

In 1780 the property at the southeast corner of Broadway and Wall street, New York, was sold for £1000, a handsome price for those days; but in 1827 it brought more than three times as much, or $18,725. At the death, in 1901, of Benjamin Douglas Silliman, a famous lawyer of New York, the then owner, the value of the property was estimated at $500,000. In 1904 it was assessed on the tax list at $535,000. On Tuesday it was sold for $700,000; yet it is a small piece of land, only about 30x39 feet, and the price paid for it is therefore about $600 a square foot. This is equivalent to about $1,500,000 for a full city lot of 25x100 feet. The attorney for the purchaser speaks of it as "the most valuable piece of real estate in the whole world." At any rate, it has been bought at what is probably the highest price ever paid for land of corresponding area in the world.—The Earth.

The best philosophy—a contented mind.

"IT'S PENNY WISE"

Policy to set out a good tree, costing good money, and then let the sun burn the bark, or the rabbits gnaw it, when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Mfg. Co., 2124 Willow st., Los Angeles.

The State Agricultural Farm

L. H. Bailey, professor of agriculture in Cornell University, delivered a lecture for the University of California summer session, recently. Part of his lecture was along the line of the needs of a State Agricultural farm, which was very pertinent at this time, as Mr. Bailey is perhaps the best man in the country to handle the question from a practical standpoint.

We can not give the whole of his lecture, only such facts and arguments as bear directly upon the selection and use of land for university purposes:

"The agricultural college is founded on the conception that education must relate itself to life. Important corollaries follow. In the first place, agricultural education should not necessarily be bound by academic methods. The teaching work in a college really divides itself into two parts, (a) the true college work, leading to a Bachelor's degree; (b) postgraduate work, leading to two degrees, the first of these being. the Master's degree, which should be given for experimental and investigational work, the work involved in the collection and accumulation of facts, etc., and the Doctor's degree, which should be given for a philosophical consideration of the facts and the collection of data.

Two great enterprises have now come into the college—the experiment station and university extension. Agricultural education also rests upon a large and quickened idea of the laboratory method. We are introducing laboratory methods into every school in the country; the kindergarten, manual training, the school garden, and science work—all mean the laboratory method. And now we also introduce the affairs of everyday life into the schools. All laboratories are pedagogically valuable in proportion as they are in vital connection with theoretical instruction.

All this brings up the whole question of the university farm. The college or university farm developed with the Land Grant Act. In its history it has gone through several phases. It was first conceived of largely as a model farm, and of course the model farms became the laughing stock of the farmers of the State; and they will always be. If they are model farms they have little pedagogical use. One farm cannot be a pattern farm for all conditions. There are thousands of model farms. Model farms are good farmers' farms. The State cannot afford to go into the model farm business in connection with university work.

In the second place, the farms came to be used merely to illustrate farm practices. In the old days we had museums in our colleges, and persons could go and exclaim as they saw the wonders. We still need museums, but we also have collections with which to work. It is not enough that students merely see things growing or see different breeds of animals. They must come nearer than merely to look; they must use and handle.

Again, college farms were sometimes run with the idea of making a profit; but you cannot run a farm with profit with student labor. If the State is to make money out of a farm, then it must not be used for teaching purposes, but must be conceived of as an out and out business enterprise.

In the next place, there was an idea that these farms ought to represent the commonwealth—that a farm should be "typical" of the State. It is a mighty poor State that can be typified in one farm. If the State wants a typical farm let it have it, but do not burden the University with it. Put it in charge of a Chamber of Commerce, or other advertising organization. Anybody can farm typical land.

Then there came the passage of the Hatch act in 1887, which established the experiment stations; and this afforded a means of utilizing the college farm. There are a good many of our institutions which are now carrying farm lands as experiment stations. Of course we should have farms for research. There are two kinds of research work on farms. One kind of research is in farm practice; the other is research in the fundamental physical, chemical, and physiological problems, which must be done on some farm directly under control.

Now we have come to the final and proper stage—the farm must then be a laboratory. Thus primarily it must be a laboratory enterprise, and the pattern and model idea are only incidental and secondary. If your people do not believe in this idea, then you must educate your people. A college farm is not primarily for the purpose of growing model or perfect crops. I should rather have the opportunity to teach one student by means of a farm than to show one hundred persons a field of perfect pumpkins.

If we study plowing in the class room, we must also study it in the field, even if we destroy a crop. We must determine and test the relation of plowing to moisture, aeration, microbic life and many other questions. It is more important that a man learn how and why to plow than it is for the college farm to grow a crop of wheat. Even if I tore up the drainage on a farm in order to teach it, I want to be able to do it. The botanist pulls up the plant to study it. In learning how to grow potatoes one should pull them up and study the root system. Not long ago I was asked how deep potatoes should be planted in a certain soil. I asked, "How many of you know whether the tubers form above or below the feeding roots." Four or five guessed, but no one knew. But on that fact depends much of the success in planting potatoes. If your students want to see a model orchard, they have a thousand of them in California. We want such an establishment as will allow us to drive our cattle right into the class room. We are this day building a class room at Cornell which will hold stock, and which has seats for the students on the sides. They will study real live cattle, not pictures and models. The young men study those cows and find out why they are good and bad cows. They examine their conformation, etc. These cows are just as much laboratory material as the plants of the botanist or the chemicals of the chemist. Next week, if we should be studying the question of beef cattle, they are brought into the building and the students study them just the same way your students study the stratification of rocks. Ten acres of land to use when I want it, and as I want it, is worth more pedagogically than a thousand acres to look at.

The value of a university farm from a university man's point of view consists in its usefulness as a means of teaching. If you do not want to call it a farm, call it land. The better it is as a farm, the better it ought also to be as a laboratory; but the laboratory utilization of it should always come first. If you are not using farms as a means of training men you are not using them for university purposes. A director of an agricultural college said some years ago when a visitor complained that he didn't consider the college farm to be a model farm, "I would rather have a good man with a flower pot in a window than have a poor man with a thousand acres of land." A university farm justified from the university or pedagogical point of view must be made a true laboratory to collate and articulate with the theoretical instruction, otherwise the future will not justify your possession of it.

The following figures are furnished by the Earl Fruit Co. showing the handsome returns that they received for fruit in the East on the 9th inst. These sales make fruit growing in California extremely profitable:

CITRUS FRUITS

By C. A. Day, Pasadena

INSECT PESTS OF THE CITRUS ORCHARDS.

The owner of a citrus orchard free from insect pests is indeed fortunate. Eternal vigilance is the price that the orchardist must pay for the continued freedom from the depredations of those insects which prey upon citrus trees and their fruits.

* * *

INJURY FROM PERNICIOUS INSECTS.

The pernicious insects which attacks citrus trees and their fruits derive their sustenance and support from the tree, diverting to their use the nourishment that is required for the growth of new wood, foliage and fruit. They prevent the growth of new wood, cut down the yield and lower the quality of the fruit.

* * *

INSECTS THAT INFEST CITRUS TREES.

Of the different insect pests which infest the citrus orchards of California, I now call to mind the following: Of scale we have the purple, red, yellow, greedy, black, soft brown, soft orange and cottony cushion scale. Of other insects we have red spider, mealy bug, orange aphids, black aphids, Fuller's Rose beetle, orange worm and thrips. A truly formidable array of insect enemies, nearly all of which have been imported into this State from other sections of the United States and other countries, through the ignorance or carelessness of those who have been engaged in importing fruit, plants or nursery stock into California. With an effective quarantine maintained in the years past, we should now be free from the scale pests which have cost our citrus fruit growers millions of dollars in remedies for their destruction and further injury to the fruit crops of years past. One reason why these foreign insects have proven so injurious to our citrus fruit interests has been from the fact that in transferring them from their native sections to this State, their natural insect enemies have been left behind, with the result that freed from these parasitic checks they have increased almost without limit.

* * *

INSECT CONTROL.

In the matter of insect control there are two methods employed. First, introduction of parasitic insects. Second, various sprays, washes and fumigation.

Nature's method of control by parasitic insects is the cheapest, and in some instances, although not exterminating the scale, keep them under such perfect control that they are no longer a factor in the insect problem. There are a number of native parasitic insects that attack the different species of scale and other injurious insects, and in some instances effectually control and keep down certain species of these injurious insects, and, in other cases, the control is only partial, and, again, wholly ineffective. In the matter of treatment of scale and other insect pests by spraying or fumigation the effectiveness of the treatment will depend upon its thoroughness and the time of application.

* * *

IDENTIFICATION AND A STUDY OF HABITS.

Every orchardist should have a practical knowledge of economic entomology and always carry magnifying glasses or lens. One a detective glass of ordinary power and another of a higher power, for close examination. The first of these, either a single or double lens, will cost from 50 to 90 cents, and the other from $1.50 upwards. The price given will furnish one that will answer all purposes for field work. Equipped with glasses the orchardist should study the insects of the orchard, learn their names and habits. Every citrus fruit grower should be able to detect on sight any of the pernicious insects that infect the citrus orchards of California. The object of this is to be able to discover any new infection of the orchard by an insect pest, new to the orchard or locality. Where the orchardist is unacquainted with names and habits of insects found in the orchard, he should secure specimens in a small box or vial and carry or forward them by mail to the horticultural commissioner of his county. An important matter is to be able to recognize each insect in its various forms of transformation, the egg, larva, pupa or crysalis, and the adult insect.

* * *

QUARANTINE THE ORCHARD.

No infected fruit should be brought upon the place. No plants, or nursery stock should be purchased without they pass a rigid inspection by a competent authority. No picking boxes or sacks in which infected fruit has been handled should be allowed to be brought on the place without being first disinfected. The county horticultural commissioner should be notified of the infection of adjoining orchards or places and a request be made for their disinfection. All this care and trouble to prevent the infection of the orchard with new insect pests is along the line of the old adage, "An ounce of prevention is worth a pound of cure." We have localities in the citrus sections of our State where the original infection of a single tree with a scale insect has been allowed to spread until it has thoroughly infected scores of orchards, that entail on the owners a yearly expense of hundreds of dollars for remedies which only partially keep the insect under control, with a still greater loss in damage to tree and fruit from the depredations of the insect. This has been especially true with the red and the purple scale.

THE CITRUS FRUIT SITUATION.

Following is an interview with A. B. Woodward, manager of the Southern California Fruit Exchange, who is probably the best posted man in California today on the marketing of citrus fruits. Our readers will find many suggestions of value in what Mr. Woodford says:

"Conditions all over the country are excellent, and the volume of fruit consumed, covering all kinds, is constantly increasing, until the business is reaching enormous proportions. This of cource applies to oranges and lemons, as well as to other varieties of fruits. Business conditions throughout the North, South, East and West seem to be improving from month to month and year to year, although, of course, the advance is more rapid in some quarters than others.

"Notwithstanding that California is constantly increasing its production in both oranges and lemons, there is every prospect that our good fruit will be taken at fair prices. We may not be always able to sell at remunerative figures the lower grades and offsizes, but fruit of good quality will, in my judgment, always be in demand. At least, for many years to come.

"Competition in oranges is largely from Florida, although, of course, there are quite heavy importations from Jamaica. It is generally reported that the Florida crop the coming year will be only about two-thirds of what it was last year, and to that extent we may expect a better market than prevailed last year for our holiday and early shipments.

"Our competition in lemons, of course, comes from the Mediterranean, and early in the present season, market conditions in the United States did not look attractive to the importers of this fruit, with the result that the amount imported was much less and we have consequently had a very much better lemon market than has prevailed for several years. If our lemon growers will take courage and raise a good quality of fruit, pick it at the proper time and care for it according to most approved methods until time of shipment, keeping the markets steadily supplied from one end of the year till the other and not rushing in and out, thus leaving openings for the Sicilians to step in and take the market, there is a great future for the California lemon and it will only be a question of a few years until California will furnish the great bulk of the lemons consumed in the United States, as she now furnishes the oranges.

"Growers in different sections of California should turn their attention to that variety of citrus fruit which grows to the greatest perfection in their respective locality, and for which the best net results are obtained. In the early days, owing to a lack of knowledge on the part of those who originally planted the orchards, the wrong variety of citrus fruit was in many cases planted. Certain sections are in the front rank in the production of navels; other sections in the production of Valencia Lates; still others in the production of lemons; the sections where each variety does best having become now fairly well defined, growers being able to judge which variety of citrus fruit will bring them the best net results.

"Altogether the time is not one of discouragement, but for renewed effort and ability on the part of all connected with the business, handling the whole situation, from the raising of the fruit, until it is finally marketed, according to the best and most approved methods."

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

THE CHAYOTE.

(Sechium edule.)

The Chayote is a tropical American vegetable (from Mexico and West Indies), closely allied to the cucumber, and the vines have somewhat the same appearance, though the Chayote is much more vigorous than its near relation. It is also much more of a climber than the cucumber and may be seen in scores of California gardens, climbing over fences, outbuildings, dead trees, etc.

One of the strangest features about the plant is that germination takes place while the single large seed is still within, or partly within the fruit. The mature seed is pushed out until about one-third of it shows, when it splits and the vine comes forth (see cut). In California the vine usually appears just before the roots, which start from the same source. The usual mode of propagation is to plant the fruit whole, leaving about one-half its bulk above the soil. The fruit will even grow when lying on a lawn with the exserted seed at least two inches above the soil, the roots reaching the earth within a few days after appearing, though the writer has seen instances where the vine has reached a length of three feet before any roots were visible.

The fruit is an excellent substitute for summer squash and by many considered quite superior in flavor. The vine makes a good climber where a rank growing, rough covering is needed for fences or outbuildings, and though somewhat tender, will, if frozen down, readily sprout again from the yam-like roots. The flowers are also rich in honey. The fruit from which our illustration was made was taken from a vine growing on the nursery of Howard & Smith, Los Angeles, where each season, the vine flowers and fruits luxuriantly. It should be given a trial in the most nearly frostless parts of Southern California, and it is probable, that when once it becomes known, it will be extensively planted.

The U. S. Department of Agriculture has issued a well-illustrated bulletin on this vegetable, from which we glean the following:

"Although of American origin and long confined to the American tropics, the Chayote has recently attained popularity in Australia and Algeria, and from the latter country hundreds of tons of the fruits are now shipped annually to the markets of London and Paris. It seems to be eminently worthy of cultivation in the Gulf States and California. * * * The annual production of Porto Rico must have a value of many thousands of dollars, although quite unconsidered as a source of wealth because the cousumption is entirely local."

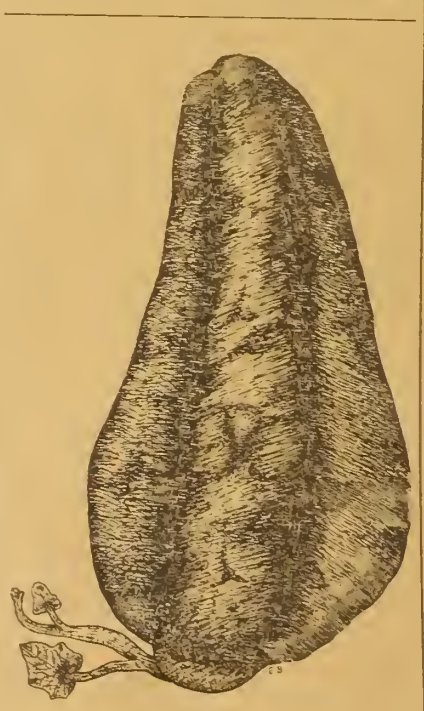
House pelargoniums should be repotted during August and a couple of weeks before the work is doue it is well to head back old or unshapely specimens.

PARKS OF THE FUTURE.

A change is coming to park affairs, the ideals are taking a more comprehensive form, and better suited to the needs of the people. As the park mission is being better understood, parks are no longer a rarity, but are common. While esthetical requirements are greater, yet they are being better adapted to everyday use.

It is necessary that what we do shall be symbolic of some thought or feeling, that it shall be a physical expression of some desire or purpose. We are not only learning these things, but also that the parks are more for the people, and that the people who rove over them are the most beautiful feature a park can contain, and that no park, no matter how barren and unsightly it may be when empty, can not be devoid of utility and beauty when filled with people enjoying themselves.

The large scenic park which came so strongly to the front twenty or



The Chayote.

thirty years ago is ever increasing in value, yet it is somewhat overshadowed at the present time by the movement in favor of small parks and playgrounds on the one hand, and the extension of the great park and boulevard systems on the other hand.

Cities are being considered more as a unit, with a civic center ever increasing in size, with radial lines of development ever extending outward, with inter-radial spaces of less value and receiving less attention, but it is in these places that parks and the quieter functious of city life should be located. Their value for parks is greater than the most costly business block. Scant sympathy is given to him who would locate a large square or park in the midst of a business district or across lines of radial growth. For there business must concentrate even as the lens concentrates the sun's rays, but parks and parkways should be located in inter-radial spaces.

The location of some parks has been such as to make them destructive and a nuisance, and full of contaminating influences. The feeling that a park must necessarily be of advantage, no matter where located, is giving away to the feeling that while a park proportionate in size and development to the area and population of the city it serves, and properly located, is of inestimable value, yet if out of balance or improperly located it may become a nuisance.

KEEP BUSY.

During the spriug and summer months, when the bushes and vines are covered with bloom, there is a disposition among home gardeners to regard their work as finished and to rest on their laurels, as it were. This is especially the case where one has other duties to perform, when an easy chair on a porch or a hammock swung between trees is more inviting. There is a tendency to neglect the flower garden, to let it take care of itself, and neglect now is more fatal than at any other period. Just a little neglect now means destruction to some of the beautiful plants that cost time and money. Neglect in watering the sweet peas will cause them to turn yellow and stop blooming. Neglect now will give the aphis and other insect enemies a chance to get in some very deadly work. Neglect in tying up the long stalks of gladiolus will cause them to fall during the wind storms. Neglect in watering the plants of all kinds will cause them to dry up, wither and die, defeating the object for which they were planted. Neglect to use the hoe will give the weeds a chance to grow and crowd out the flowers. In short, neglect of any kind will undo much of the good work that was done earlier in the season.

TRAINING PLANTS.

The best time to train a plant is while it is young; then it is tractable and easily handled. After it has made considerable development it is hard to manage, and much of its work is wasted because its growth has to be sacrificed to bring it under control. By training the plant while it is young it can be made to grow along lines desired, consequently there will be no vitality uselessly expended. Very few plants will grow into symmetrical shape if left to pursue their own inclinations. They will be apt to grow up tall and lank, having but two or three branches where there should be a dozen. If the top of the young plant is pinched off branches will soon start and if these are pinched back when three or four inches long they will produce other branches. The result will be a bushy, compact plant with a good many flowering tips, whereas, if left to itself, there will be a few branches, and a small quantity of flowers.

FIRST CULTIVATED ROSES.

It is said that the first cultivated rose was planted in Belgium in 1522. The damask rose was taken to England from France in 1573, the moss rose about 1724 and the China rose fifty years later.

If the chrysanthemums are troubled with insects it is a good plan to apply tobacco tea to them.

AUGUST A TIME FOR SOWING.

August is the time to prepare for the second California springtime which the beginning of the rainy season ushers in. The character of the preparation depends upon the location and also upon the moisture available. The irrigated garden has possibilities far beyond those of the rainfall garden; therefore, if you have water, clear away the debris of the summer crop, soak the soil deeply and, as soon as the soil works well, fork it over thoroughly, fine the surface and sow all kinds of hardy vegetables and annual flowers which you desire. Many tender things can also be sown in August if you have a location free enough from fall frosts to allow them time to mature. In the hottest interior situations, however, August sowing does not succeed so well as near the coast, because some seedlings cannot endure the dry heat even if soil moisture be adequate. On a small scale a lath or cloth shade may protect them without too great outlay. On the other hand, August sowing of same things in the interior is often very satisfactory. Garden beans for instance are often more prolific in the moderated heat of the autumn than near the summer solstice and one can have good sweet corn, cucumbers, cantaloupes, etc., in the autumn also, unless the frosts come too early. It is interesting to try many other things with an August start on irrigated land, and a beginner will often be surprised and delighted over his achievements if he dares to defy the warning of the wise acres who tell him he must wait for the fall rains.—E. J. Wickson in Sunset Magazine for August.

Bone dust or bone flour makes an excellent fertilizer for potting soil. Four to six ounces of finely ground bone flour may be added to a bushel of potting soil, mixing thoroughly. The dust or flour should be used for this purpose, and not the bone meal, which is much coarser.

Let the poppies transplant themselves; don't try to transplant them.

General Agricultural Notes

GRICULTURAL INSTRUCTION.

The Experiment Station Record, in speaking of the present satisfactory movement toward a more general introduction of elementary agricultural instruction, says:

The progress which is making among leading educators in this country in the conviction that agriculture should be given a place in courses of study for rural communities, was evidenced at the forty-fourth annual convention of the National Education Association, held at Asbury Park, N. J., early in July. Elementary agricultural instruction was one of the prominent subjects of discussion at the convention, and it enjoyed the distinction of special mention in the annual address of the president of the association, delivered to thousands of teachers at the opening session. This was perhaps all the more significant as coming from the superintendent of schools of New York City, Dr. William J. Maxwell.

Doctor Maxwell commended the teaching of agriculture in public schools in strong terms, pointing out its advantages to the people in rural communities, and to the nation as well, in the greater efficiency of its agricultural population. He declared the teaching of agricultue in a practical manner to be just as necessary for the rural school as manual training is for the city school.

Most important of all, however, was the report of the committee on industrial education in schools for rural communities. The report of such a committee was in itself a significant fact, and this was further emphasized by the prominent place given it in the programme and discussions of the association. The report was an elaborate one, comprising nearly a hundred pages.

In general the committee called attention to the difficulties of securing the efficient teaching of agriculture with the present organization of our public school system. It discouraged the wholesale introduction of agriculture in country schools having only a single teacher. "To require by law that every country school teacher shall give instruction in the elements of agriculture is, in the judgment of the committee, a serious mistake. It will simply result in another failure to be added to the failures recorded in France, Ireland and Canada. Such failures are likely to discourage further immediate efforts and prevent the present undertaking of what might otherwise be done."

In the discussion following this report Prof. W. M. Hays made a strong plea in favor of schools specially adapted to the needs of country life. He called attention to the fact that thus far the public high schools have almost exclusively shaped their curricula with reference to the needs of the people living in cities, with the result that the country children attending such schools are drawn away from the farm. While recognizing that under present economic conditions a considerable portion of the country youth would naturally be drawn to the city, he urged that education for the country people should be of such a character as to maintain farm life at a high level and make farmers more efficient and progressive.

Dr. A. C. True, of this office, pointed out that leaders of agricultural progress are now thoroughly in earnest in demanding that instruction in agriculture shall be made a regular part of our public school system, and that this demand shall be met by teachers and school officers. He stated that enough had been done to show that such instruction could be made successful in elementary and secondary schools, and that it only remained to work out a feasible plan for the general introduction of agriculture into the rural schools. The wide interest which has been aroused, the experiments which are making with different methods, and the intelligent study which is now being given to the subject by educators, make the probable realization of this end not far distant.

GATHERING STATISTICS.

The last legislature passed a bill providing for the gathering of statistics in the different counties of the State as follows:

"It shall be the duty of the board of supervisors of each county, on or before the first day of November of each year, to supply the secretary of the State Agricultural Society, upon blanks to be furnished by him for that purpose, statistics showing the products grown, produced or manufactured in said county, for the year preceding, and the expense thereof shall be a county charge, to be paid as other county charges against the county."

Acting under the requirements of this law, the secretary of the State Agricultural Society, Mr. Albert Lindley, has had blanks prepared which will be supplied to the supervisors of each county and which they will be required to have filled out. This is a work which has long been needed, as it has been almost impossible heretofore to obtain much more than an estimate of the products of the State, especially of the agricultural and horticultural outputs. The law required the assessors of the various counties to obtain the number of trees and vines in their counties, but this has either been ignored or done in such a manner as to be absolutely worthless. In many cases, the owners believed that the information was required for purposes of assessment and have falsified the reports to the extent of their conscience, which in most cases was very elastic. Under the new law it will be possible to obtain from each county accurate information which will be of great value to the grower and shipper and, as there can be no suspicion that it is for assessment purposes, it will be easier to obtain accurate information.

SKIM-MILK PAINT.

An eastern exchange has the following recommended for a cheap paint:

A use to which skim-milk, sour milk, butter-milk, or even whole sweet milk is often put is paint-making, yet this product of the dairy, says the Scientific American, makes possibly one of the most enduring, preservative, respectable and inexpensive paints for barns and outbuildings. It costs little more than whitewash, provided no great value is attached to the milk, and it is a question whether for all kinds of rough work it does not serve all the purposes and more of the ready-mixed paint, or even prime lead and paint mixed in the best linseed oil.

It should be made as follows, and no more should be mixed than is to be used that day: Stir into one gallon of milk about three pounds of Portland cement and add sufficient Venetian red paint-powder to impart a good color. Any other colored paint-powder may be as well used. The milk will hold the paint in suspension, but the cement being very heavy, will sink to the bottom, so that it becomes necessary to keep the mixture well stirred with a paddle.

Six hours after painting this paint will be as immovable and unaffected by water as a month-old paint. It is a splendid preservative, and I have known buildings which were painted twenty years ago in this manner, in which the wood was well preserved. Whole milk is better than skim-milk, as it contains more oil and this is the constituent which sets the cement. With the addition of a small quantity of crude carbolic acid it makes a fine disinfectant and is in every way suitable for dairy work.

FOREST PRODUCTS.

The annual value of the forest products of the United States, as enumerated in the Twelfth Census, is nearly 575 million dollars. If to this were added the value of the firewood, farm material, and other forest products for which no returns are available, a very much larger figure would be shown. Thus, as a direct source of wealth the forests of the country rank nearly with the mineral products as second to the farms. In addition to monetary value, the forests of the country have an immense, though not exactly calculable, value as a source of future supply and as a protective covering for watersheds.

PRACTICE MAKES PERFECT.

Oh, what a tangled web we weave
When first we practice to deceive.
But when we've lied a year or two
How slick we are! I am. Aren't you?

Silk Culture in California.—The Department of Agriculture at Washington ought to pay more attention to the silk industry in this State. It is doing something, but the opportunities are so abundant for a valuable industry that it seems too bad more encouragement is not given it in the way of supplying conditions to expand its growth.

If the Agricultural Department would establish stations where egg production could be carried on, it would not be many years until the silk industry would become one of the leading enterprises in California. At present there is no source for egg production in this country. Eggs are imported, as a rule, from France and Italy, and they are so imperfect that results obtained from them are most unsatisfactory. Eggs bred in California are perfect, the worms healthy and strong, the raw silk of superior quality, which, worked into reeled silk and sewing silk, is the best made.

Secretary Wilson is endeavoring to import only first class eggs, but the experiments in the past have not been satisfactory to those who have used them. A modern silk station, with a competent instructor in charge, with mulberry trees grown especially for feeding, would soon send the silk industry to the front in California.

Mrs. Carrie Williams, of San Diego, probably one of the best informed of the silk growers in this country, tells us that the government pays $5.00 per ounce for eggs and the demand is greater than the supply. Manufacturers import $50,000,000 of silk annually, which they call reeled silk to evade the duty of 25 per cent. This is really raw silk, but under the duty it comes in as reeled silk and this discrimination is what retards the silk industry in America. Notwithstanding the drawbacks to the business there is considerable silk culture in California. It is conducted on a small scale, of course, but those engaged in it find it not only intensely interesting, but lucrative. If conditions were right, that is, if the Department of Agriculture would put in stations where the soil and climate are conducive to the growth of the worm, and supply those stations with competent instructors it would not be many years before California would rival the best silk producing nations of the world. Mrs. Williams assures us that Southern California can produce better eggs than any State in the Union or country in the world—for that matter. The mulberry tree, if care be taken with it, makes a healthier leaf in California, on which to feed the worms, than any other place where it is grown, France even not excepted.

As to the profit in silk culture it needs only to be said that the raising of the worm is comparatively inexpensive after the station has been fitted with the necessary appointments to make its growth assured. The expense comes in where skilled labor is required to manufacture the silk. If labor could be procured in this country as cheap as it can be in France and Italy, we would be able to compete with the oldest silk making countries of the world. But until we have stations and instructors to teach young women the process of the culture, the industry is largely at the mercy of foreign help and this has proven too expensive to permit of extended operations. At Petaluma, in Sonoma county, there is a silk mill employing one hundred hands and we are advised that the enterprise is proving a success.

If silk could be made here under as favorable conditions as it is in some of the countries of the world, it would become one of our chief industries in California and the South. Note the profit which attaches to silk culture. One pound of reeled silk will make from five to fifty yards of silk goods, or twelve yards of grosgrain. One pound is worth $5.00 and fifty yards of grosgrain is worth $150. Eggs are worth $5.00 an ounce, which alone would make a handsome profit under favorable conditions. In 1865, we believe, when the silk worm disease ravaged Europe, Japan realized $85,000,000 in a few years from eggs alone. So it will be seen that the government might well devote much more time and money to exploiting the possibilities of the silk industry in the United States, for once we have established the culture it would be a source of immense revenue to the country in the saving of money now paid for our silk purchased abroad.

* * *

Great Irrigation Schemes.—Following the announcement of the fact that the Owens river is to be brought into Southern California for irrigation purposes, comes the statement that the government has decided to condemn Indian valley, the richest in Plumas county, supporting three towns of about 3000 population, for the purpose of irrigating the lands in Sacramento valley, a distance of some eighty miles. Engineers are at work on the plans now and it is proposed to dam the Little Feather river, holding the water in the valley, to be used as the demand may be made. The reservoir will be twenty miles in length, with an average width of five miles. While the cost to the government will be very large the territory watered will include some of the finest agricultural lands in the State. These lands heretofore have been unproductive for general farming, but under the irrigation ditch proposed will form one of the richest and most reliable sections of country in the State. The government is alive nowadays to the importance and necessity of extending irrigation to bring under permanent cultivation the unoccupied lands of the West. The growth of our population on the Coast, demands increased acreage, lands at prices which will justify their occupation by farmers with limited means who desire to operate on a circumscribed scale. Watered lands in California are now practically taken up, their price is beyond the ability of the average man seeking a home, he can not acquire them, but he will be able in unoccupied territory to gain a foothold, under the government plan of irrigation, at prices he can command. It is to encourage the building up of the State that this irrigation scheme is advanced. When the valleys of the North and the deserts south of the Tehachapi are watered, as they soon will be, we shall realize what California under favorable conditions can do. Our population will be numbered by millions and our products fill the land of all countries.

* * *

Property Enhanced by Trees.—The Cultivator has, at different times, discussed at length, and scientifically, the value of tree planting as moisture producers. It has also urged the pecuniary advantages derived to a farm and to a town, by liberal, intelligent selection of trees for street beautifying. We are glad to note that this subject is receiving the attention of others, also authorities, on the question. One of the most recent discussions comes from the California Promotion committee, which has issued a pamphlet entitled "Street Trees in California." The author of this valuable bulletin is Professor Jepson, of the University of California, instructor of botany. In this pamphlet he discusses at length the property value derived by tree planting to cities and towns, as well as rural districts, and the suggestions he offers are well worthy of careful consideration.

"From the standpoint of both the individual and the community," says Professor Jepson, who has given special study to this subject, "there is no other asset that can be put upon the land of municipal and agricultural California so valuable as trees. And there is particular need for planting trees in what is practically waste land, the curb line of streets and the sides of many county roads. Such trees, properly planted and persistently cared for, are valuable to all as well as to one, for several good reasons. As a purely commercial matter it is now well known that street and road trees increase property values. Authenticated cases are at hand where naked farm land of superior value has sold at less price than inferior land fronted by lines of roadside trees. And this difference is, to a certain extent, justified because in these days of increasing wood scarcity, trees have in themselves a great value. As a matter of comfort, too, street trees are a boon in a land where for five or six months cloudless skies prevail."

Along the lines suggested by Earnest Braunton, in his articles published in the Cultivator, Prof. Jepson calls attention to certain rules which are everywhere applicable to the selection, arrangement and planting of trees on streets in town and along the public highways, and his recommendations are of great value to all civic improvement clubs which are taking this subject under consideration.

Deciduous trees, evergreen trees and palms are the three classes recommended for general use. A list of deciduous trees, with the advantages and disadvantages of each as a street tree, takes up many pages of the pamphlet.

The Cultivator would suggest that those interested in the subject of tree planting send for a copy of the pamphlet and study its suggestions, as to what to plant, and how to plant, that they may intelligently work the coming season. Tree planting is one of the most needed improvements in California, not only to beautify our towns and highways, but to enhance the value of our homes.

* * *

A Lesson to be Heeded.—New Orleans is again experiencing a scourge of the much dreaded yellow fever. Some years ago that city was visited by the fever and several hundred victims died from its ravages. At that time sanitary measures were resorted to which effectually stamped out the plague, or so nearly stamped it out that it has not appeared as an epidemic since. At that time the health officers of the State and City of New Orleans thoroughly renovated the sewers and drain pipes in houses, and by the free use of quick lime in the marshes about the city, disinfected the unhealthy places. The streets were cleaned and alleys made free of decaying vegetation, as well as of every sort of refuse substance which would breed bacteria of the yellow fever type. The result was that in one season the plague left, and not until this year has it appeared in an alarming form. Of course, there have been cases annually where the fever developed, but it was not permitted to gain any headway, because the health board exercised great caution in cleaning the city.

It appears, however, this spring the efforts of the health board relaxed, the city and country about it became dirty, the rice fields were not looked after nor the sewers and drain pipes in houses inspected as heretofore. This letting down of the bars of caution, which was occasioned by a desire to retrench in public funds, has proven a serious lesson to New Orleans. How much has been gained by so doing will be seen in the results which the city of New Orleans is now experiencing. Reports are to the effect that business is almost wholly suspended, entailing an enormous loss on the commercial interests of the city and country round about. What is true of New Orleans may be true of every city in California. We are in the line of every plague which finds its greatest stimulant in tropical climates. Our railroads lead directly from southern cities, while our ports are open to ships which visit almost every land and bring the products thereof to our doors. We ought always to bear these things in mind and to keep our coast line towns and cities clean and sanitary in every particular, as it is possible to make them. The money New Orleans saved in retrenching in its health department has gone out a hundred fold in the loss of business the city has sustained in the few weeks yellow fever has scourged it. The lesson is one to which San Francisco, Los Angeles and San Diego may well give heed.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Lump sales of the apple crop in orchards in the Pajaro valley this season are more than for many years past.

Plans are on foot to organize a new association to be known as No. 14 of Queen Colony Fruit Exchange at Corona.

The dried apricot crop around Bloomington was all pooled and sold at six cents per pound and shipped last week.

A twelve ton carload of mixed fruit from Visalia sold in the East last week for $2197. This is the highest price of the season.

A. L. Rice, foreman of a big prune orchard at Rockford, Tulare county, is trying the experiment of killing squirrels by putting dynamite in the holes.

According to one authority on fruit shipping, if early rains do not come to prevent there will be shipped about 1800 carloads of grapes during the present season.

The Oppenheim Fruit Co. at Lodi has offered $280 as prizes, above the wages, to be given to packers receiving the highest sales for their packs during the season.

Prune drying around Healdsburg is on in full blast this week. Brown Bros. will operate very heavily in that section this season and expect to dry over eight hundred tons.

Some crops of prunes in the Pajaro valley have already been sold on the tree, to be delivered after they are dried, the contract price being at two and a half cent basis.

At the annual meeting of the Covina Fruit Exchange, held last week, Dana C. King, of Azusa, was elected to the position of manager and secretary, vice H. G. Chesebro, resigned.

Orchardists of Toluca valley commenced shipment of peaches to Los Angeles last week. They are receiving $21.50 per ton for two-inch freestones and $33 for clingstones.

The apricot growers of the Hemet valley will have about fifty tons of fruit to market this year. Six and a half cents in car lots has been offered, but they are holding for seven cents.

The Fresno Democrat states that the fig crop will be as much as thirty-five per cent short in that county this year. Packers are offering two cents and it looks as though the price would go higher.

The Highland Messenger says that from the present outlook of the orange crop for the season, it will be considerably earlier than usual and that sizes will be exceptionally large. The crop in most orchards is very heavy.

The two canneries at Visalia are handling nearly all of the peach crop grown there this year, very little fruit being dried and the prediction is made that dried peaches will bring a much higher price than usual this year.

The Hollister Free Lance says that the prune crop in San Benito county will go about sixty-five per cent this year. The price started in on a two and a quarter cent basis, but has steadily risen to three cents, at which figures growers have sold liberally.

Reports from Porterville citrus section state that the orange crop will not be as large this season as last. Between eight hundred and one thousand acres were set out to oranges this year and indications are that large acreages will also be planted next season.

The Russian River Fruit Association of Sonoma county has in their pool this year about two thousand tons of cured fruit, chiefly prunes. The object of the pool was not to fix and maintain prices, but to have the prunes on hand and sell them when the market was at its best figure.

The Citrus By-Product Co. of Southern California, with headquarters at Pomona, has been organized. Capital stock is placed at $25,000, $7000 of which is already subscribed The more companies of this kind that are organized to use up cull fruit, the better for the fruit industry of California.

The validity of the recent order of the Board of Supervisors of Tulare county, prohibiting the importation of grape vine roots in that county is to be tested by a Fresno grower. This order was passed to shut out the phylloxera, if possible, but a similar ordinance passed by Fresno county some years ago was declared unconstitutional.

Dudley Moulton, horticultural commissioner of Santa Clara county, is in Southern California, collecting scutellista and other parasitic and predaceous insects. Though a young man, Mr. Moulton has already made for himself an enviable reputation as an entomologist. His recent article on thrips in the Cultivator has been widely copied and commented upon.

It was announced last week that a monopoly in the grape business covering the entire output of the San Bernardino valley had been effected by the California Wine Association, signing agreements to pay $11 per ton for all the grapes that growers could furnish them. Since that, outside buyers have been in the field offering $12 per ton, and the rumor is that the price may go another dollar higher.

At the meeting of the State Board of Trade held in San Francisco last week, at which were prominent fruit growers from all over the State to discuss the reciprocity question, the following resolution was passed: "That this Board has been in the past and is still opposed to any modification of the impost duties upon the productive industries of California, whether by the way of reciprocity or by legislation."

In spite of the great shortage in early shipments of cherries and later of pears, the green fruit shipments from this State up to August 9th were greater than those of last year by over one hundred cars. The figures being for last year 2821 cars shipped as against 2928 this year, and at the rate the prices are holding up in the East, the shipments will be much heavier at the end of the season than for several years past.

The Visalia Delta says that during eight days in succession there have been shipped from that city sixteen cars green fruit that brought over $1450 a car. One of these cars sold for $1762 and another sold for $1980. The Delta further says that these last two cars show profit of $1200 and $1500 each and that as a result of such high prices times will be exceedingly good in Tulare county the coming fall and winter.

The sudden winking out of a promised bumper crop from Georgia, Maryland and Delaware and other peach producing States in the East, has had the effect of booming California products to top notch on all tree fruits. During the past week or two the demand in the East has practically exceeded the supply. The fruits now being shipped from the central part of the State to meet this demand are peaches, plums, prunes, Bartlett pears and early grapes.

AGRICULTURE.

Experiments in growing canary seed in the San Juan valley were not successful this year.

Cantaloupe growers in the Lindsay section have cleared from $100 to $150 an acre net this seaon.

Barley yielded a heavy crop in the San Juan valley this year, but wheat was very light, occasioned by the rust.

The Lodi Herald says that prominent men of Stockton have decided to incorporate a company to build a factory for drawing and milling flax.

The cantaloupe growers about Coachella are preparing for a fall crop of "cants" to be ready for market about October 1st. About one hundred acres are planted.

The total grain crop on the big San Joaquin ranch in Orange county will amount to 175,000 sacks, practically all barley. The crop is commanding a price of about $1 per sack.

Oakley Bros. of the Imperial valley announce that they will engage extensively in experiments with sugar beets the coming year. Beets will be planted every month in the year that the best time to plant and harvest may be ascertained.

A dispatch from Ventura county states all the black-eye-bean farmers of that county will make a good clean up this year. The price now being offered is $3.25 per hundred. Last year some 50,000 sacks of this variety of beans were grown there, the price then being only $2.25 per hundred.

The Pajaronian says that harvesting the seven hundred and fifty acre crop of horse beans has been in progress in the Pajaro valley the past week. The yield was rather small, being from one-half to three tons per acre. Most of the crop has already been contracted at prices ranging from $1.40 to $1.75 per hundred pounds.

The State Board of Agriculture has sent to every board of supervisors in California blanks on which to collect important data regarding agriculture, horticulture and manufacturing interests of the State. The statistics to be collected will show at a glance the exact position occupied by each and every county. The classifications include cereals, hay, fruit, vegetables, nuts, brandies, live stock, poultry, dairy, fish, forests and manufactures, with a special schedule for productions shipped out of the State.

LIVE STOCK.

The Kings county creamery has been leased by the Raab Creamery Co. of Los Angeles.

A special feature of the Central California fair to be held in Hanford September 9th to 14th will be a dairy auction sale of live stock which will enable exhibitors to dispose of stock.

Wm. Clark, a prominent sheep breeder of Sonoma county, has been over the State looking for thoroughbred Ramboulette ewes, which he was unable to find, and has since sent to Missouri for a lot to breed from.

A company has recently been incorporated with a capital stock of $10,000 to conduct a creamery at Laton. Between four and five hundred cows have been pledged to furnish milk so that the success of the enterprise seems assured.

The Santa Maria Valley Live Stock Association has been organized to work in harmony with the county association, for the general protection of live stock interests. But its chief object will be to prevent the further spreading of Texas fever.

The supervisors of Sacramento county last week passed an ordinance regulating the conduct and conditions of dairies and markets for live stock, so as to provide for the protection of live stock from contagious and infectious diseases and enforce quarantines.

MISCELLANEOUS.

El Centro is the name of a new town to be started four miles from Imperial.

The supervisors of Riverside county last week voted $12,000 to be expended in oiling roads.

The bee men of Ventura county have been offered four and a half cents per pound for honey, but are holding the crop for five cents or better.

Residents of Owen valley, Inyo county, are protesting vigorously against the proposed action of Los Angeles city in taking their water supply.

D. F. Marikle, a bee man in San Diego county, has secured from one hundred stands ten thousand pounds of honey, or an average of one hundred pounds per stand.

Two new wineries have just been completed near Healdsburg. One is for Lawrence Moss, with a capacity of 40,000 gallons and the other for an Italian by the name of Denucci.

The California Traction Co. has filed articles of incorporation with the Secretary of State. The company will begin building at Stockton and will branch out in various directions to Modesto, Lodi and eventually to Sacramento.

Plans for the largest single irrigation plant ever undertaken by the Federal Government have been completed for the district known as the El Paso system. The plan is to construct a dam near Engle, New Mexico, one hundred miles north of El Paso, on the Rio Grande, by which water enough will be saved to irrigate 180,000 acres in New Mexico and Texas, and also 70,000 acres in Mexico. The cost is placed at $7,200,000.

C. H. SESSIONS, ASSOCIATE EDITOR

REGARDING HOG CHOLERA.

Editor Cultivator:—I have received the Cultivator for some time and am well pleased with it. I have been reading your articles on hog cholera. I will mail you in separate envelope Farmers' Bulletin No. 24 from the Agricultural Department, and ask you to kindly publish, although the formula is the same as you published some time ago.

I have tested this remedy as a preventive, having used it for over five years, and never lost a hog from cholera. Any person raising hogs and feeding the compound every 10 or 12 days will never have cholera. When I moved where I am now, a little over four years ago, the man that was on the place lost fifty or sixty hogs with cholera and buried them wherever they died. Consequently my hogs uncovered three that were buried together, and ate all they wanted before I knew it. I never lost nor had a sick hog, for I was feeding the compound, and fed it once a day then for some time. I had the druggist in Merced put it up, and he sells the 10 lbs for $1.50. My neighbors two years ago lost nearly all their hogs.—W. L. Weaver, Merced.

The formula which Mr. Weaver mentions has been published twice in the Cultivator, but after his unqualified approval we republish from the bulletin.

Wood charcoal	1 pound
Sulphur	1 pound
Sodium chloride	2 pounds
Sodium bicarbonate	2 pounds
Sodium hyposulphite	2 pounds
Sodium sulphate	1 pound
Antimony sulphide (black antimony)	1 pound

These ingredients should be completely pulverized and thoroughly mixed. In case there is profuse diarrhoea the sulphate of sodium may be omitted.

The dose of this mixture is a large tablespoonful for each 200 pounds weight of hogs to be treated, and it should be given only once a day. When hogs are affected with these diseases they should not be fed on corn alone, but they should have at least once a day a soft feed, made by mixing bran and middlings, or middlings and corn meal, or ground oats and corn, or crushed wheat with hot water, and then stirring into this the proper quantity of the medicine. Hogs are fond of this mixture, it increases their appetite, and when they once taste of food with which it has been mixed they will eat it though nothing else will tempt them.

Animals that are very sick and that will not come to the feed should be drenched with the medicine shaken up with water. Great care should be exercised in drenching hogs or they will be suffocated. Do not turn the hog on its back to drench it, but pull the cheek away from the teeth so as to form a pouch, into which the medicine may be slowly poured. It will flow from the cheek into the mouth, and when the hog finds out what it is, it will stop squealing and swallow. In our experiments, hogs which were so sick that they would eat nothing have commenced to eat very soon after getting a dose of the remedy, and have steadily improved until they appeared perfectly well.

This medicine may also be used as a preventive of these diseases, and for this purpose should be put in the feed of the whole herd. Care should of course be observed to see that each animal receives its proper share. In cases where it has been given a fair trial, it has apparently cured most of the animals which were sick and has stopped the progress of the disease in the herds. It also appears to be an excellent appetizer and stimulant of the processes of digestion and assimilation, and when given to unthrifty hogs it increases the appetite, causes them to take on flesh, and assume a thrifty appearance.

Success or failure with this remedy depends largely upon the manner in which it is used. If it is improperly administered, or the hogs left out in storms and compelled to remain day and night in mud six inches or a foot deep, under the necessity of searching through this mud to find an ear of corn in order to get anything to eat, the farmer might as well save his money and let his hogs die, as nothing we have been able to find will save them under such conditions. If, on the other hand, the sick animals can be made reasonably comfortable, and given soft, easily digested food to eat, the medicine, of which we have just given the formula, may be used with confidence that it will give good returns for its cost and the trouble of its administration. Apparently, it is not as beneficial in swine plague as in hog cholera.

In treating hogs for these diseases it must not be forgotten that in nearly all cases there is more or less inflammation of the internal organs, and particularly of the stomach and intestines. To treat such diseases successfully the animals should be kept dry and comfortable, and where drafts of air will not blow upon them. The food must be such as can be digested by the irritated and inflamed organs which are charged with this function. With these general principles in mind the farmer may undertake to treat his sick hogs with a fair prospect of success. He may not save them all, but he should be able to preserve a good proportion of them.

The question now arises, What disposition should be made of the hogs during treatment, and what sanitary measures should be adopted in addition to the medical treatment? When the hogs are first found to be affected with hog cholera or swine plague the lot or pens where they have been confined should be disinfected by dusting plentifully with dry, air-slaked lime, or by sprinkling with a 5 per cent solution of crude carbolic acid. The animals should then all be moved to new quarters. If possible, the sick and apparently well should be separated before they are moved and then put into different lots. This is not essential, but it is an aid to the treatment. The hogs should be kept in dry lots, or pens, where there is no mud, and, above all, no stagnant water. It is well to keep these lots disinfected by the free use of air-slaked lime or carbolic acid.

It is not expected by this supplementary treatment that the hogs will be entirely removed from the influence and attacks of germs. This is not necessary. The number of germs which gain access to their bodies may be so reduced by following the plan, however, that the vital force of the system, assisted by the medicine, is sufficient to overcome them.

During this treatment the hogs gain a marked degree of immunity. No doubt this is the results of attacks of the disease from which they recover. This recovery is in spite of the continued infection of the premises, and even though the hogs which have gone through the outbreak are apparently well and thriving, new hogs added to the herd are liable to be attacked. For this reason five or six months should be allowed to pass before any new hogs are purchased and brought on the premises or before any are sold to be put among other lots of hogs. Young pigs born under such conditions in some cases are able to resist the infection, while in other cases they may suffer severely or die.

If any hogs die during the progress of the outbreak their carcasses should be immediately burned or deeply buried and the places where they have lain or the ground over which they are dragged should be disinfected with carbolic acid or lime according to the method already mentioned.

* * *

Prevention.—The swine grower should use every effort to prevent the introduction of the contagion of these diseases upon his premises. If he purchases hogs from a distance or sends his own animals for exhibition at the fairs, he should insist upon their being transported in clean cars, which have been disinfected if they have previously carried swine. When new hogs are brought upon the farm or when his own return from exhibition, they should be rigidly quarantined

and not allowed to come in contact with the other hogs on the farm for at least six weeks.

Hogs should not be allowed to run at large in the vicinity of railroads over which swine are transported. Infected hogs are frequently shipped to market, and there are sufficient droppings from the cars in which they are carried to scatter the contagion along the railroad for the whole distance they travel.

When these diseases appear upon a neighboring farm precautions should be adopted to prevent the introduction of the contagion. No one should go upon the fields or into the pens where the sick animals are and then go to another farm where the disease has not appeared. Remember that a particle of manure or dirt the size of a mustard seed from an infected farm is sufficient to start an outbreak that will destroy a herd of swine. A particle of that size may be carried upon the shoes of a visitor, upon the foot of a dog or other animal, upon a wagon wheel, or in a multitude of other ways. Non-intercourse at such a time is therefore the safest rule.

Experience shows that hogs kept up in a pen or small lot are less subject to infection when cholera is in the neighborhood than those which are allowed to run at large or in the fields. It is, consequently, advisable, when there is reason to fear this disease, to keep the hogs in a small enclosure, which should be as dry as possible and disinfected once a week with air-slacked lime or a 5 per cent solution of carbolic acid. A small quantity of carbolic acid (3 to 15 drops according to age) in the drinking water tends to prevent infection and may have a beneficial influence upon the course of the disease.

Other points on prevention are, "Breed stronger constitutional animals by using strong, mature breeders. Feed variety, wheat, barley and other grains, and do not confine too closely to corn."

THE OLDEST DOMESTIC ANIMAL.

Of all domesticated animals the sheep has from time immemorial been most closely associated with mankind. An erudite author sixty years ago, having laboriously collected an assortment of allusions to sheep made by sacred and profane writers, concluded that "the history of these animals is so interwoven with the history of man that they never existed in a wild state at all. Biblical history from the time of Abel is full of allusions to the flocks which formed the chief possessions of the Jewish people and their neighbors. The spoils of war and the tribute of vassal kings largely consisted of sheep. Thus we read Mesha, King of Moab, was a sheep master, and rendered unto the King of Israel 100,000 rams with the wool.

"LOADED WITH POISON."

The Fresno Republican has a somewhat extended article referring to the loss of large numbers of cattle in the San Joaquin valley, and says that some authorities there have maintained that the cause of the loss is due to the stock eating Johnson grass and that the grass causes the death of the stock on account of the large content of prussic acid. It is claimed that scientific people have made an examination and that some of the grass has been submitted to the chemistry department of the State University and that the local scientists unqualifiedly claimed that the prussic acid has been found in grass and that "the University chemists are said to have reached the same conclusion." The paper then adds:

"Prussic acid in green feed is not a new thing. A few years ago cattle were dying in Kansas from eating green sorghum, and tests disclosed the presence of the poisonous acid in deadly quantity.

As is well known Johnson grass was introduced into this country by Professor Sanders, now in San Quentin—not, however, for introducing the Johnson grass, although there are those who think the jury couldn't get the Johnson grass out of its mind. It's very hard to get out of any place.

Sanders proved that it contained more milk-producing ingredients than any other known fodder.

The farmers—relying upon his knowledge—he was an accomplished botanist—planted the un-uprootable stuff.

But, alas, the cows wouldn't eat it. They formed a milk maids' union of some sort and declared they'd die first. Many of them did.

Sanders was appealed to. He explained that his knowledge of the grass was purely scientific. In the laboratory it showed up strong. But, he explained, he didn't say that cows would eat it—that was up to the cows."

Of course, it may be that there is a poisonous substance in the Johnson grass. It certainly is exasperating enough in its general characteristics to make it easy to believe such a proposition, at least. We hope, however, that such will not be found to be the case.

LONG DISTANCE DAIRYING.

Editor Nelson of Farm, Field and Home directs attention to the fact that the hand separator and central creamery have become great in their consequences for far outlying districts. Not every district suitable to dairying is thickly enough populated or has enough dairy spirit to support a creamery or skimming station. But now from the farthest edges of Nebraska, for instance, and as far distant points in neighboring States, individual ranchmen are shipping cream to the great creamery at Lincoln. Sweet and fresh, the cream is skimmed immediately on milking, and before it could have time to rise under old methods, delivered at a creamery four hundred miles away. The cost of shipment—borne by the creamery—is 35 cents per eight gallon can, a trifling freight when it is considered that this is only a little over 4 cents for every can of milk put through the separator. For 200 miles the freight is a little over 2 cents for the cream of every eight gallon milking. The ranchmen receive an average of more than $4.80 for eight gallons of cream, or the equivalent of over $0.60 per can of milk. This is not counting the skim milk retained by them in its most valuable condition and fed at a minimum value of 15 cents per hundred pounds.

Milk production on a large scale need no longer be confined to suburban districts or others thickly settled. The 60 cents per eight gallon can, plus the value of the skim milk, is the equivalent of that received for years by many wholesale dairies close to the great cities. And it is not a temporary good price. Creameries exclusively are supplying our foreign butter trade. They have brought our butter up to a high state of excellence, and now our foreign trade is increasing. The Dutch, Swiss and Danes are the buttermakers of Europe; but their dairy resources are not ours. Another competitor is Russia, but the quality of American butter gives us an advantage over her. Their hardest problem, the creamerymen declare, is not to find a market for their butter, but to find butter for the market. They want all the cream they can get—much more than before, since the old markets are growing decidedly, and since butter can now be sold where before the oleomargarine makers palmed off their product.

DAIRY PROGRESS AND ENLIGHTENMENT.

We fear that eastern dairy farmers are not keeping track very closely, of the development of the dairy industry in the far west. For instance Humboldt county, California, is one of the best dairy organized counties on the Pacific coast, yet the industry may be said to be in its infancy there. Last year it produced butter that sold for $1,162,793; condensed milk, $62,569; condensed cream $50,496; total $1,175,858. Yet, with all this increase in the production of milk that is taking place all over the country, the increase of the consumption of dairy products has more than kept pace with it. This is particularly true of the consumption of milk, which has been due very largely to the agitation of dairy subjects in the public prints. More has been printed and read on dairy questions in the metropolitan newspapers in the past fifteen years than in all the previous history of the country.

The authorities of all the leading cities, as a consequence, have been stirred to the enactment of laws compelling the production of healthy milk and its strict sanitary care.

This movement has been going on all over the land and has resulted in increasing the confidence of the consuming classes very greatly. As a consequence the consumption has increased with the increase of confidence.—Hoards Dairyman.

WHAT DOES IT?

When a man has studied buttermaking till he is master of the science you can not keep him down. It is brains, just brains, that makes things come his way, writes a correspondent of the Creamery Journal. It is not the State he works in, the coal he burns, the tub he uses, or any other insignificeant thing that makes a man a winner or keeps him down. If there is anything that has an influence on the way medals go, it is in the oil the buttermaker uses. The man who uses lots of kerosene oil has a good chance to win. Oil used in the night lamp will have more influence on the product of the creamery than anything else. Study, think and work. Burn the midnight oil.

A recent number of Hoard's Dairyman contained a table summarizing the year's work of 100 herds of cows, containing 1894 head, in Vermont, at a creamery. The table showed that sixty-nine per cent of the owners lost money on their cows. That is, 69 out of 100 owners received less from the creamery per cow than it cost to keep the cows. Have you that Babcock test, and do you know that your cows are wealth producers and not merely star boarders?

Peter C. Kellogg, known also under his pen name as Hank Comstock, died at his home in Montclair, N. J., in his 68th year. Mr. Kellogg was one of the famous auctioneers and cattle men of his time, and left a name of strict integrity.

It is true that sheep will eat up and convert into a valuable product much coarse food that would otherwise be wasted. This is only a greater reason why they should be fed grain with sufficient regularity to equalize the rations so as to get the greatest good from the whole.

STOCK EXHIBITS AT THE STATE FAIR.

Besides the exhibits at the coming State Fair of California stock, the announcement is made that L. V. McWhorter of North Yakima and W. M. Caruthers of Chatteroy, Wash., are going to show their herds in competition with those of this State and the East. Both McWhorter and Caruthers are extensive breeders of shorthorns, and they announce they will send large herds. Another large breeder of cattle is Mr. Irwin of Minneapolis, who is going to show his herds at the Lewis and Clark Exposition. Secretary Lindley is now in correspondence with Mr. Irwin in the hope of inducing him to stop over in Sacramento and exhibit at the State Fair, as several other eastern breeders have announced their intention of doing.

Besides cattle from other States, many fine horses from the East will be exhibited, among them are McLaughlin Bros., of Kansas City, Mo., dropping off with forty head of beautiful Percherons, Belgians and coach stallions. These handsome animals were exhibited at the St. Louis Exposition last year, at which they took many first prizes.

Crough & Son, also extensive eastern breeders of the same types, will show at the State Fair, en route to Portland. Clyde Chipman, one of the best known breeders in California, is also going to the Lewis and Clark Exposition, and will enter his Percherons in the State Fair competition.

The Lafayette Stock Farm of Lafayette, Ind., will make a special exhibit of fifty head of fine draught horses, which will be the largest exhibit by one owner made at the fair.

Landis Bros., of Orangevale, representing the Greeley Horse Importing Company of Greeley, Ia., will have on exhibition seventeen high-grade draught horses. In this number are several prize winners at the St. Louis Exposition last year.

One who has practiced it for ten years says that for scours in pigs, give the sow, in milk or slop, two tablespoonfuls of baking soda. From one to two doses generally stops the scours. Give twice a day until pigs are well.

The man or woman who sets out to be a dairyman must love his work. Unless he does, failure lies just before him.

It is just as necessary to have fine form in the female as the male, as no male is endowed with sufficient prepotency to overcome all the imperfections found in the female.

While bran may be a part of the ration of all classes of live stock, it should be fed in connection with ground grain or cut feed.

When given reasonably good management and care, sheep for the food they consume give the greatest returns both in money and fertility.

A fleece of sheep wool is the whole of the wool, which is taken from the animal at one shearing.

Animals are fed for profit and it is desirable to increase that profit to largest limit.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

WORMS IN FOWLS.

I had hoped to write on the subject of the dry feed hopper method of feeding but must postpone it for another week. Meanwhile the following letter demands an answer and as it is on a topic which may prove of help and interest to many of our readers I will make the reply longer than the Editor's Question Box could contain:

"Will you please tell me through the poultry department of the California Cultivator what will cure chickens having worms? I have killed three young White Leghorn fryers and have found both bowel and tape worms in each one. One of the tape worms was about from eight to twelve feet long. Chickens, about 200 young ones hatched this spring, are on barley field range and I feed bran, wheat, Egyptian corn, bone meal and blood meal. I have 42 ducks 11 weeks old and they are inveterate feather-pullers; especially do they keep the wing feathers pulled out. Can I do anything to overcome this bad habit? Thanking you in advance for your assistance and trusting you will be able to find space to answer soon.—C. W., San Bernardino.

* * *

Answer—Personally I have had no experience with tape worms, so I look for a reply to your queries in the books of Dr. Salmon, Dr. Sanborn, Dr. Woods and have also consulted a medical friend and feel that with all this knowledge to back me I can answer you conclusively.

Tape worms in fowls, resembling tape worms in the human family, are taken into the stomach in the shape of small tiny grubs, these having been hatched in an animal of some kind, usually beef or pork. Your fowls, I suspect, have eaten them in the meat which you have fed to them. When present in large numbers these worms cause a diseased condition known as taeniasis, which may end fatally. The following are the most prominent symptoms: listlessness, loss of appetite, the fowl mopes, and becomes emaciated. Diarrhoea is frequent.

* * *

Treatment.—The infested birds should be confined in small coops and the droppings watched to make sure that all the worms and their heads are voided. All the droppings from these birds should be burned. One of the best remedies is the fluid extract of felix mas, the male fern. From six to twenty drops, according to size or age of the bird, in a teaspoon of castor oil, after fasting for twelve hours or more. Two hours after giving the male fern, give a light mash containing for each bird one tablespoon of castor oil. Bruised garlic bulbs given after starving the birds twelve hours and then followed by a tablespoon of sweet oil will prove effective in some cases.

There was brought to the Reliable Poultry Journal office, a bottle of alcohol containing a tapeworm three feet long which came from a Golden Wyandotte hen. The worm was complete, head and all. The hen in question ate heartily but lost flesh and gradually weakened. The owner could not discover what was the matter with the hen. She had no cold, ate well, but became distressingly poor and weak. Finally he thought of worms. Acting on his theory, he kept her without food for thirty-six hours, then gave her a full feed of stewed garlic, cut in short lengths. She ate heartily of this, and the next day the owner had the three foot tapeworm in alcohol. The hen began to mend immediately, regained her normal flesh and was soon as well as ever.

* * *

Round or Thread Worms.—These are the most common and most injurious to poultry. There are about a dozen or more varieties of round worms parasitic in poultry, and most of these live in the intestines, some in the proventriculus, some in the gizzard and in other mucous parts. With the round worms the sexes are separate, the female worm generally being larger than the male. The adult worms usually live in the digestive canal. The eggs and embryo worms are usually transmitted from one fowl to another through the drinking water and food. Worms feed on the organic juices of the body, a few of them live on the blood of their hosts, but the majority feed on the fluids in the digestive canals. They have great tenacity of life, particularly in the egg and embryomic state, and can remain for a great length of time undeveloped. The most common variety of round worms affecting poultry are the white worms or heterakis, which make their home in the upper portion of the intestines near the gizzard. The round worm varies in size from one-third to five inches in length. Its color is white. The head is pointed like the sharpened end of a pencil, the tail blunt like the end of a finger. These worms develop directly from their eggs, which are eaten by the fowl. My acquaintance with these worms resulted in a loss of about two hundred and fifty fine chicks from six weeks to ten weeks old. I noticed the chicks acting as if sick. They appeared sleepy, sat in a corner, feathers dull and ruffled, head hanging down or held under the wing, listless and not much appetite; when roused and made to move they seemed stiff in the legs, and some had spasms; some were ill several days, some died after a few hours illness, or in one spasm. I was at my wits' end. I held several postmortem examinations and discovered the worms and then proceeded to try remedies. I invoked the aid of several medical works on the subject, found that most of them recommended santonine two grains, or about that for each bird, adding it to the mash and putting in half a teaspoon of castor oil for each. But lots of the little fellows were too sick to eat and I did not know which of the others had worms and which had not until it was almost too late. I had about seven hundred chicks and could

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

not imagine what caused the trouble, for the brooder house and little yards were immaculately clean. They had been infested by neighboorhood pigeons, that not only devoured the food, (a pigeon will eat as much as a hen) but also killed some of the little chicks, picking them up by the nape of the neck and shaking them until they were dead. One day I noticed worms in the pigeons' droppings squirming on a board, and the mystery of the infection was explained, a vigorous war commenced; in one day fifty pigeons were trapped inside the brooder corral.

The chicks were all removed to fresh ground and by the advice of a doctor I put turpentine in the drinking water, thirty drops to a quart of water, renewing this three times a day, giving no other water. At the end of a week all symptoms of worms were at an end and I had no more trouble. The brooder corrals were first disinfected by a two per cent solution of carbolic acid, then air slaked lime was scattered over them; this was dug under; and then a crop of barley was planted in them, the brooder houses were also thoroughly disinfected and sprayed, and not used again for four or five months.

If I had but a few chicks affected I would give each from six to twenty drops (according to age) of turpentine in a teaspoonful of castor oil, or on a piece of bread, followed by a dose of castor oil. Santonine is also effective if given with oil. Some recommend assafetida and others garlic and I think they might prove good, but I have not tried them.

The tapeworms must be taken into the system in animal food, especially in uncooked or slightly cooked beef. I do not know if they could possibly exist in the cooked beef scrap or animal meal.

* * *

EDITOR'S QUESTION BOX.

Poultry Plant.—(A. D. S.) As an interested and enthusiastic reader of your columns in the Cultivator week by week, and from which I obtain many useful points on the care of poultry, I venture to ask for some information on the following points: (1) How many hens will a house 24x10, 8 feet high in front and 5 feet in rear accommodate? (2) What distance apart should the roosts be? (3) What distance from ground should roosts be? (4) In ventilating from foot of building would a one foot space all round the building be sufficient? (5) How many hens do you recommend keeping in one flock, and what house space for them? My hens are White Leghorns. I trust I am not encroaching too much on your time with this rather formidable list of questions, but my appreciation of your helpful hints must be my excuse.

Answer.—The amount of floor space needed per fowl will depend on the care the birds receive, the breed, the purpose the birds are kept for, and how much space and opportunity they have for outdoor exercise. Your house should hold comfortably about fifty Leghorns. They should be divided into two flocks of twenty-five each, the house also being divided. (2) The roosts should be from fifteen to eighteen inches apart and the same distance from the wall. The roosts can be two feet from the ground for Leghorns. (4) From six to ten inches all round the building is enough ventilation. Or one whole side of the house can be left entirely open. I recommend not more than twenty-five hens in one flock, as they do best in small flocks. If you could conveniently divide your roosting house into three, I think you might house seventy-five or eighty Leghorns, if they have good large outside yards.

* * *

A Poultry Plant.—(Mrs. A. W., Fresno.) Would be very glad to receive through the Cultivator plans for a five acre poultry ranch, in regard to convenience. I mean by this to have runs and roosting houses, runs for alfalfa, location of windmill or engine, feed house, incubator cellar, brooder house, walks, etc., and how many hens could be kept on such a place?

Answer.—With the limited space of the Editor's Question Box I could not do justice to this subject. You had better buy Captain Mitchell's most excellent book, "A Practical Poultry Plant," price $1.25. It contains all the plans you need and is thoroughly practical. For sale at Cultivator office.

* * *

Indian Runners.—(I. M. R.) Will you kindly answer the following questions in the Cultivator? I have started to raise I. R. ducks, but have been rather discouraged by having a neighbor tell me that there was no sale for them in Los Angeles markets. Is it true? My eggs I bought from a woman who got her eggs from you. I have a chance to get drakes from another flock which was also originally from your stock. Will it do to mate them to my ducks? Do you think I can make ducks pay where I have to buy all their feed? Am feeding a mash of cracked corn, bran and Calfalfa meal, with meat scraps. Is it true that I. R. ducks only lay nine months in the year? If so, at what time of year do they rest?

Answer.(1) There is always a market more or less good in Los Angeles for ducks or for anything; just at present there is not much demand and ducks are very unprofitable things to hold over. (2) Yes. I had four different strains of thoroughbreds, not related, so the chances are that yours and your friend's are not related. (3) No, not unless you can sell them at eight or nine weeks old, not older. (4) Indian Runners lay only nine months in the year. Mine averaged two hundred and thirty eggs apiece. They rest in September and October.

* * *

Corns—(S. A. F.) Can you tell me what to do for my chickens, as three of them have a growth, corn or something in the bottom of their feet, and a lump or two on their toes. Do you think it is caused from too high perches, or is it a disease? At any rate I lowered the roosts today. I keep the White Rocks and the White Leghorns—one Rock and two of the others are affected. If there is a remedy, would like to know it, please.

Answer.—Your chickens have corns, which will eventually lead to "bumble-foot." Corns are a thickening of the skin on the under surface of the foot, the result of long pressure, irritation and bruises. Corns are generally caused by too small or sharp edge perches, which compel the fowls to grasp them tightly in order to maintain their position. This firm grasp, continued night after night, affects the circulation, irritation and inflammation is set up and results in a thickening of the skin. A similar condition may be caused by high roosts, the birds alighting upon a stony surface or hard floor.

Treatment.—The perches should not be over two feet from the ground, about three inches wide, with round edges, the floor covered with sand or earth, so that the feet will not be bruised. The affected birds should have the feet soaked in warm water, and if the inflammation is high, a little baking soda added will help. The thickened skin should be pared off without causing bleeding, and boric ointment applied every night until the corn is cured, or the corn may be painted with tincture of iodine.

* * *

Turkeys Dying.—(M. D. G.) We have about seventy-five nice healthy-looking turkeys, but every few days I notice one seems tired and seems to grow weaker and in three or four days they die. Their appetite is good until they are too weak to eat. The droppings first look whitish, then turn yellow and even green, sometimes. The turkeys have a free run in alfalfa and grain fields, also grasshoppers in abundance. They are about two-thirds grown and seem to be doing fine until taken sick. Do not feed any grain now, as they don't seem to need it. Can it be caused by need of grit? The land is very sandy here but little gravel of any size. Can you tell me the cause of trouble and a remedy? I have been very successful in raising turkeys since reading in the Cultivator an article headed "Turkey Lore." Had been in the habit of over-feeding (as so many do who don't read the Cultivator). I find that young turkeys need but little feed when they are raised with turkey hens and range in alfalfa fields. Will salt poison fowls? My turkeys may have eaten salt in the pasture.

Answer.—I am sorry about your turkeys. I much fear it may be enteritis, a disease which usually comes from impure water, or water fouled by other animals or ducks. It is an infectious disease. I would advise you to give the whole flock pounded charcoal and plenty of grit, and for any that ail a liver pill and a pill of two grains of assafoetida. It is possible it may be the salt you mention, or the lack of grit, but I fear it is impure water. Otherwise your feeding and care seem ideal.

* * *

Turkeys.—(Mrs. J. C.) I am a reader of the Cultivator; have taken it for several years, but I have failed to find out just exactly what I want to know. I have been raising turkeys for the last two years. Last year I had thirty, this year seventy, as nice a flock of turkeys as any body wants to look at. What I want to know is this: Do you think the hens, of which I have two of last year, would be good for another year to breed from? They have laid two hundred eggs this year. Laid all the time they were hatching. Last week for three or four days they didn't lay, but this week they are laying every other day again. I never had hens lay like these do, and I am afraid that next spring, when I want them for hatching purposes they won't lay. What do you think about it? I would be very glad if you could give me some information on the price for breeding purposes. I have had several say to me, I want some of your turkeys to breed from. Last year I sold twenty-four to one man for Thanksgiving; they weighed 285 lbs. and were eight months old. I have the Bronze and the Mammoth Bronze.

Answer.—I congratulate you on your success with turkeys. I would most decidedly keep your two turkeys and also one or two of your own young females—early hatch—and get a tom. See advertisements in this paper. Or else keep your own best tom.

* * *

Fowls Dying.—(Mrs. J. M. B.) Your letters in the Cultivator have been so much help to me. I write for further information, I am so distressed about my poultry, and as I am a "tenderfoot" from the East, I don't know what to do for them. They seem to be in perfect health at the last feed in the evening, and I find them in the morning almost dead. I can see nothing to denote sickness. I have fed them well on grain, meat and vegetables. Corrals are kept perfectly clean and lime, ashes and kerosene oil used on floors and perches. Some of them are moulting, but not these that have died. If they were old hens I would not so much wonder at it, but some of them are this year's chickens and others last year's.

Answer.—I wish I could enlighten you but cannot unless you can describe some of the symptoms a little more definitely. Possibly the fowls have worms. Study my article and try to find out. Or perhaps they are getting poisoned. Has your orchard been fumigated?

* * *

Limber Neck.—(D. P. B.) I have always read your articles in the Cultivator very carefully on poultry diseases and cures, but find nothing just like mine, unless it is limber neck. I have always had good success with poultry till now, some of my pullets are afflicted one at a time occasionally. At first they don't care to eat, in a few hours they can't hold up their head. I examined them for lice; some I would find two or three lice on their head, some none. Some I greased their heads and then keep them wet, as the head seems very warm. In a day or so they would seem all right. Others I just wet the head and they got well. One seemed to have a looseness of the bowels and I gave it baking soda and wet its head and it got well, although it lay apparently dead part of the time. They stand as long as they can, and their heads hang limp. Last night one died and I opened it and examined it closely. The bowels were nearly empty, except the caecea or caecum, which was full of soft green stuff. The liver seemed natural but the gall bladder was full. The heart and lungs were all right. I feed wheat in straw in the morning, so they can scratch and Midland poultry food No. 4 at night, with about one-fourth Calfalfa meal mixed in. All they will eat, and they have cabbage most every day. They run on the 10-acre orange ranch, so have plenty of shade, but there is no weeds or green stuff. They have plenty to eat and the best of water three or four times a day in clean vessels, and good clean houses to roost in; no mites. The old hens are not affected, although fed on same feed.

Answer.—Your young fowls have what is called limber neck. This comes from a disorder of the nervous system. It usually comes from disturbances of the digestive organs, from indigestion, from worms, or from unusually hot weather. A remedy that has been successfully used is: Hyposulphite of soda. Dissolve one teaspoonful in half a cup of water, give a teaspoonful to each affected fowl every two or three hours. The following is said to never fail: Give the affected bird a piece of assafoetida about the size of a green pea. Repeat the dose the second day. It is pleasant to read in your letter how well you care for your fowls.

Cholera among fowls may be known by the greenish droppings, drooping, and intense thirst. A fowl with cholera drinks often and remains long at the fountain. When you are sure that cholera is in your flock, add a teaspoonful of carbolic acid to three pints of water, and give no other water to drink. If the fowls have indigestion, add twenty drops of nux vomica to each quart of drinking water.

The best statesmanship—self-government.

The weather and crop conditions for the week ending August 14 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—Warm, clear weather continued during the first of the week, becoming cooler toward the close, with high fogs at night and morning in the coast districts. Desert storms accompanied by heavy rain occurred along the eastern boundary near Needles, causing washouts on the railroads.

The grain crop is nearly all harvested and threshing is progressing rapidly. In most sections the yield is below expectations and only in a few places up to average. Barley has turned out better than wheat. Oats are light in all sections. The hay crop is the best for several years, both in yield and quality. Hops made good growth during the week and in some sections prospects are better than at any time during the season; picking will become general within two weeks. Sugar beets are yielding a heavy crop in the Santa Maria district. Beans are doing well, but the outlook is not as good as earlier in the season. Corn, potatoes and vegetables are in good condition.

Grapes are rapidly maturing and picking is in progress. Raisin grapes have a high percentage of sugar and a heavy yield is probable. The heat during July injured some varieties of grapes, but the yields will probably be fully average. Many varieties of deciduous fruits are yielding better than estimated. Walnuts are improving and in some sections the crop will be up to average. Olives and citrus fruits are in good condition.

Eureka Summary.—Foggy along the coast throughout the week. Grass is green, and vegetables are in good condition. Hay harvest is mostly finished; unusually heavy crop secured. The apple crop is about average, but in some localities almost a failure.

Los Angeles Summary.—Continued cloudy weather along the coast and fair in the interior. Water plenty. Favorable reports of next orange crop continue.

THE WALNUT CROP.

According to Horticultural Commissioner L. G. Yates, who has just returned from a trip through the Lompoc district, the outlook for walnuts in that valley is very bright. The crop conditions are much better than at Santa Barbara, and there seems reason to believe that the valley may become a walnut district of considerble importance.

Mr. J. B. Neff of Anaheim, was in our office Monday and stated that in his judgment the walnut crop of Orange county would be about 25 per cent short of last year, though it would be three or four weeks yet before the size of the crop could be definitely stated.

"I often wonder," said Boroly. "what my ancestor, Adam, said when he first met Eve."

"Was he an ancestor of yours?"

"Certainly."

"Then he probably asked her to lend him $10."

CONSERVING WATER.

The experiments that have been carried on for the government at Riverside this summer by J. Edwin Roadhouse, under the direction of Prof. Fortier, to determine the amount of loss in irrigating water from evaporation, by seepage and that given off by trees, have been brought to a close. In an interview with Mr. Roadhouse this week he stated that the experiments have proven very successful, though at this time he could not give out the figures. The saving of water by orchardists through the dust mulch Mr. Roadhouse says will give water enough to irrigate all Southern California, and by this method alone the danger of a water famine can be averted. Orchardists will be interested in the bulletins on this subject.

HEAVY LAYERS.

W. W. Howard of Los Angeles, tells us that he has a pen of 30 White Leghorn 1904 hens that have laid in nine months and a half from 185 to 207 eggs each, and are still laying. This is a remarkable record. Who can beat it.

The S. J. Smith Machinery Co., of Los Angeles, has secured the contract for putting in the machinery for the new water and electric light plant at Signal Hill, Long Beach.

* * *

Another of the Cultivator's advertisers has just landed a nice contract. The Western Gas Engine company, of Los Angeles, is to furnish nine engines to the company constructing the government dam above Yuma. At first the construction company (a New York concern) had determined to use steam power, but after inspecting the gas engines of the Los Angeles firm, ordered nine of their engines.

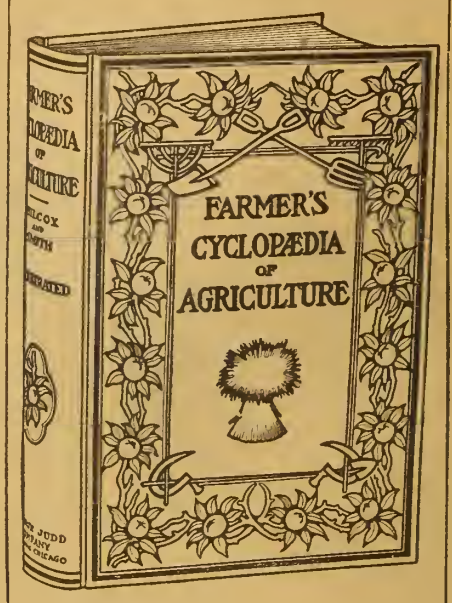
PAINTING AND PAPERING.

In preparing for painters and paperhangers, there are several things to be borne in mind. Cleaning for painting should be thoroughly done as dark marks show through. Old wall paper should be entirely removed from a wall before the new goes on. Accumulated layers of paper, each with its own store of dust and microbes, is most unsanitary. The easiest way to loosen old paper, is to set an uncovered boiler of steaming water in the room, then close doors and windows and let the steam do its work. If there is any danger of moths or bugs, stop up all cracks with putty or moistened paper, forcing the latter in with the blade of a knife.

Prepared stains for floors, furniture and woodwork are now so plentiful and cheap and put up so conveniently for amateur use that many persons like to freshen up their rooms without calling in outside talent. If one has time and strength this is usually quite satisfactory. Do not try, however, to use stains that are not mixed with oil, as they will lose color and fade instead of growing deeper with age. If preferred, stains may be prepared at home with very little trouble.

"The hen stood on the garden lot,
Whence all but she had fled;
And didn't leave a planted spot
In the early onion bed.
With vim she worked both feet and legs,
And the gardener says 'he bets
She was trying to find the kind of eggs
On which the onion—sets.'"

Farmer's Cyclopedia of Agriculture



A Compendium of Agricultural Science and Practice on Farm, Orchard and Garden Crops, the Feeding and Diseases of Farm Animals, Dairy Farming, and Poultry in the United States and Canada

Authors: EARLEY VERNON WILCOX, Ph. D.
CLARENCE BEAMAN SMITH, M. S.
Assistant Editors in the Office of Experiment Stations, United States Dept. of Agriculture

The World Moves

and whoever would not be left behind must lay hold on every means that enables him to move with it. As a basis of one's efforts nothing is more essential than the possession of a good work of reference

Adapted to the Conditions Peculiar to California and Adjoining States

The Farmer's Cyclopedia embodies in its many articles, most of the results of years of painstaking work at the California and neighboring State Agricultural Experiment Stations. It is thus, in effect, both a digest of local and state experience, and a compendium of general knowledge, all of which will prove of indispensable helpfulness to everyone in this section.

The Last Twenty Years of Progress

have measured more changes and recorded more advances in every branch of agricultural science than have been achieved during the hundred years preceding. During all these years no reference book adequately covering the subject has been issued.

The plan of this work is most comprehensive. Every article has received the most careful preparation at the hands of the authors, who have enlisted the co-operation of the highest authorities in the various departments. The greatest educators of the world, representing every branch of agriculture, here unite in one immense faculty to present directly and plainly the pertinent facts of their specialties. Every statement is authoritative and absolutely reliable.

If you wish to know about field crops, garden vegetables, fruits, nuts and other economic plants, farm animals, dairy farming, poultry, also manures, fertilizers, principles of feeding, soils, drainage, irrigation, spraying, veterinary medicines, etc, etc, it is here. Everything concerning farm matters is treated with great thoroughness, though without undue fullness. We claim for it the unique distinction of presenting for the first time, in a carefully arranged and perfectly accessible form, an accurate summary of every subject of interest to farmers, etc.

Over 6000 Topics Indexed
A Wealth of Illustrations

An important part of this work is its very complete and elaborate index, with cross-references under both scientific and common names, so that any information wanted can be found at once. There are between 6000 and 7000 topics covered in these references, making the most perfect index to agriculture ever attempted. It contains 700 royal octavo pages (9½ x 7 inches) and nearly 500 superb half-tone and other original illustrations. Type, paper, printing and binding are all in the highest style of the bookmaker's art, worthy alike of the well-qualified authors, the enterprising publishers, and the industry of agriculture.

PRICE IN HALF MOROCCO, $4.50

To Cultivator readers we make this proposition:—Fill out and sign the enclosed coupon and mail to this office and the book will be delivered postpaid at once and your Cultivator subscription advanced one year.

CUT OUT AND MAIL THIS COUPON AT ONCE

CULTIVATOR PUB. CO., LOS ANGELES, CAL.

Please enter my name for one year (NEW OR RENEWAL) and send me the Farmer's Cyclopedia of Agriculture, half morocco. For both together the price to be $5.00, which I agree to pay as follows: $1.00 on the first day of next month and $1.00 on the first of each of the succeeding four months. Until the $5 is paid in full title to the Cyclopedia to be vested in you.

Queries and Suggestions

DRAINING TO REDUCE ALKALI.

We have a request from John Anderson, Hynes, requesting information as to manner of reclaiming the lands about Salinas from alkali by drainage and general information as to cost and detail of the work. We have no direct information in this particular case and invite any subscriber in that section who can supply us with such knowledge to give it to us. Meantime, we have taken steps to secure information along the same line from other sources. We may say, however, that it has proved one of the most profitable means of reclaiming alkali lands, some cases having made most valuable tracts from land which was before comparatively worthless.

PRUNING BERRIES.

Editor Cultivator: I noticed in recent issue of the Cultivator that the present is the best time for pruning blackberries and other vines. Will you kindly inform me in your next issue whether I can defer pruning until the plants are dormant in the winter and then use the stalks for making cuttings for extending my plantings? Will they take root and grow or is that not the way the vines are propagated? In others words, will they grow from cuttings at all?—J. D., Compton.

The old canes which have been bearing the fruit of this present season will be of no value to you whatever for the purpose of propagation. In fact, it will be far better for the plant to have them removed at once, leaving the new, or this year's growth, still standing. The difference between the two you may determine by the fresh, bright appearance of the new stalks and the browned and partially shriveled appearance of the old stalks. In addition the stems of the fruit may still be seen on the fruit-bearing spurs. These should be cut back to the ground and then the new cane which can still be left standing may be tied up to stakes or, if you are anxious, as you say, to secure extension of your plantings as rapidly as possible, you may reproduce the raspberries and dewberries by layering. That is, take the long, slender canes, laying them as flat on the ground as possible, and cover at the various joints with dirt. From these joints will spring small shoots and roots will be formed so that by the time the wood is hardened in the fall they will be in nice condition for transplanting. The blackberries usually furnish sufficient sprouts coming up about the plant stalks to give any reasonable number of plants.

MEASURING HAY IN THE STACK.

Editor Cultivator: Can you tell me method by which alfalfa may be measured in the stack? If you can, please give me dimensions per ton.—E. B., Mecca.

It is impossible to give the dimensions of a ton of hay exact, for the reason that condition of hay when put up, the kind of hay, whether well settled or soon after stacking, and other conditions must be considered. For instance, alfalfa hay in well settled stack will weigh more than will barley hay. But, approximately, well settled hay requires four hundred cubic feet per ton, or an average of about five pounds per cubic foot.

To secure the number of cubic feet in a stack multiply together the length, breadth and height to "eaves" (or angle where stack begins to slope) plus one-half the vertical distance from level of eaves or angle of stack to crest—all in feet. Divide product by number of feet allowed for a ton (about four hundred). Or, if slope from ground to crest is uniform, multiply together the length, breadth and one-half the vertical height, all in feet, and divide by number of feet to the ton. The space occupied by a ton of hay will vary with the depth of the mow or stack and the kind of hay, whether coarse and hollow-stemmed, or fine and compact. In that respect one's judgment must be called upon to aid in the estimate.

INTENSIVE FARMING.

Some time since the Cultivator received the following letter from a subscriber at Modesto and it was submitted to Mr. Lobingier, manager of the Barbour ranch, at San Gabriel. The letter and Mr. L.'s reply are as follows:

Editor Cultivator: Some time ago you published an article in effect that the idea so prevalent, that a man must cultivate a large number of acres was not correct. Amongst other things, you mentioned onions and berries as profitable. I would like some information, details in fact, in regard to raising onions; what kind, and how, and when to plant. I had good success in raising the red onions from seed sown in August and transplanted in February, but find a very limited market and poor price, and they tell me that is not the kind to raise, but I cannot get much information on the subject.

As to berries. My soil is not ideal, but I think I can raise strawberries and blackberries, but my raspberries are proving a failure. The young plants do finely for a while, until the hot sun and the withering, blasting California northwest winds get in their work, then the leaves blight or burn around the edges, gradually getting worse until the whole plant dies—they did that last year. Is there any help for it? They get plenty of water every week; they are Red Cuthbert.

If you will give some information or tell me where to get it, you will greatly oblige a new settler.—Modesto.

Any one who can have onions ready for market from April first to June 1st can be pretty sure of high prices for his crop. We tried to do this by sowing seed of the new White Queen. September 20th, but it was seven or eight weeks too late. The crop was not ready until July and by that time the market was overstocked and at this writing (August 10th) we still have the crop unsold. If one cannot succeed in getting the crop to mature at the date I mention, so as to sell as early onions, it would be better to grow some variety like the Australian Brown, sowing in February and have the crop mature in the early fall—when they can go on the market during the early winter. The Australian Brown is a fine keeper and popular in the market.

I prefer to sow the seed in a seed bed and transplant the young onions. While this involves a good deal of labor in the beginning, there is less weeding later on, and no thinning at all. No one should undertake to grow onions—nor any crop—on a large scale, without previous experience. Begin in a small way and learn the "know how" by practice.

I have been very successful with the variety known as Prizetaker, but it is best for local markets, as the trade classes it with the varieties that do not keep well and do not care to buy in large lots. The quality and appearance is number one and the yield enormous—under favorable conditions. Every one contemplating onion growing should get the "New Onion Culture" by Mr. Griener. It costs but fifty cents and is full of information useful to beginners. It can be had of Johnson & Musser, Los Angeles.

I hold very strongly to the view that intensive farming and gardening is the only kind that pays. It is not the area one works, but the manner of working it that counts. If I were to tell Cultivator readers that we set an acre of strawberries last August and September, and the yield thus far is 31,350 baskets, which sold for five cents per basket, average, he might think it a California story. It is; but it is a true one (31,350x.05 equals $1567.50. To produce such results one must have the right conditions and know how.

Regarding the raspberries I cannot give much encouragement to any one attempting to grow them under such conditions. The whole raspberry family delight in a moderately cool atmosphere and not to wind. I should not attempt it in any of the interior, hot valleys of California.—Q. A. L., Barbour Ranch, San Gabriel.

The San Diego County Honey Producers' Association held a meeting recently, at which they decided to store their crop of honey at San Diego, rather than sell at prices now offered. The next meeting will be held September 2d, at El Cajon.

ALL crops should be well supplied with a fertilizer rich in POTASH. The benefit will be seen in the grain and also in the crops to follow.

"Plant-Food" and "Potash in Agriculture" are two books full of interest to every progressive farmer; we will mail them to you free of all cost.

THE VILLAGE RUBBERSMITH.

Under a spreading blacksmith sign,
The village blacksmith sat;
He heard the chuf-chuf-chuf and said,
"Where is my business at?
The road is full of horseless things,
And bikes and such as that."

The smith was deeply in the dumps;
Ah! that was plain to see.
His wink-eye winked a knowing wink
Up at the chestnut tree;
And then he said, "These horseless things
Have put a horse on me."

And through his crisp and curly hair
His sinewy hand he ran.
Says he, "I'll get some different tools.
As well as any man
I'll mend a punctured rubber tire—
I'll charge whate'er I can."

Week in, week out, from morn till night
His bellows blows no fires.
Instead it feeds a rubber tube,
That blows up rubber tires.
He has a tank of gasoline,
And cement, pipes and wires.

And children coming home from school
Rubber in the open door,
They rubber at the rubber tube
A-rubbering 'round the floor,
They rubber at the rubbersmith,
Who rubbers tires that tore.

He can't go, Sunday, to the church
For that's his busy day.
Some city chauffeur's in the lurch,
And here is work—and pay
The chauffeur buys some gasoline
And chuf-chufs on his way.

But never mind, his daughter's there,
Up in the choir stand;
And as she holds the hymn-book high,
Shows diamonds on each hand;
For daughter's buying jewelry
And Dad is buying land.

Repairing and pumping and mending;
Onward through life he goes,
Each morning sees some tire break,
Each evening sees it close.
Something mended, somebody done,
Puts money in his clothes.

Thanks, thanks to thee my worthy friend,
On the lesson I'll meditate.
All must at times get different tools,
This world will never wait;
If we would live the strenuous life,
We must keep up to date.

—J. N. H., in Metropolitan.

Told by the Schoolmaster

"Good morning, Ralph."

"Good morning, Mr. Blackman," I responded, in tones as cordial as the greeting of the principal of the Northville grammar school, adding pleasantly, "For a schoolmaster you look very happy."

"I am happy this morning, Wintersvale; verily, the happiest man in the commonwealth, I believe. If you were not a newsgatherer, ready to put everything you hear into type, I would tell you about it, for I do not forget that you were for years one of my boys; yes, and one in whom I was especially interested," he said, giving my hand an earnest pressure.

A flood of pleasant memories carried me back to my schoolboy days, and I said warmly, "Thank you, Mr. Blackman; but please don't think all that is told men goes into type. Long ago my conscience decided the battle between fidelity to a paper and fidelity to a friend. I have never betrayed a confidence, and I never shall!"

"Then Ralph Wintersvale will succeed," said the master, earnestly. "It it not far to the school house," he continued, "so come up to my office and I will tell you a story. A part of it, as you will perceive, is not for the local paper, but outside, if the telling will benefit you any, repeat it and welcome.

"Did you know Mark Dittman?" he asked, when we were seated in his cozy office.

"No, sir, but I have heard of him,' I answered.

"Yes, I guess you have," he chuckled, "and are destined to hear a great deal more; but what I am going to tell you now, Wintersvale, is the cause of my happiness. Some poet says:

"Each life has moments that are never forgot,
Which brighten and brighten, as time steals away;
They give a new charm to the happiest lot,
And shine on the gloom of the loneliest day!"

To my mind the sentiment is perfect. Just such moments in my life occurred fully fifteen years ago. I was delving hard at my office work on the morning the fall season opened, when Miss Turnbull entered: 'I am at a loss what to do,' she said. 'A great overgrown boy is here from some district school. In point of years he certainly is old enough for my class, but as to his mental development, I wish you would be the judge. He has but one answer to everything—"I dunno,' and he looks "I dunno," too,' she ended, rather ungraciously for her.

"Now, Wintersvale, I have always held to the idea that there is no such a thing as a dull boy. Who is he, anyway? Ask a chemist and he will tell you he is a boy whose brain cannot absorb the infinite complications of chemistry. A carpenter will answer that he is the boy who lacks the knack of handling tools; and so on down the whole string. Each man would say that he is the boy who is unable to master that individual's specialty.

"To me, there is no 'dull boy,' nor have I ever heard of an instance of so called dull boy, where it did not turn out a case of someone trying to fit a square peg into a round hole.

"'Send him to me,' I said, and when he entered I saw at a glance that Miss Turner's picture was hardly overdrawn. I realized that the lad through various causes, had reached that deplorable point where self-effort ceases, but in full sympathy with him, and determined to make him think himself capable, I said cheerily, "Good morning, my lad, what is your name?'

"'Mark Dittman,' he replied, rather sullenly.

"'Come,' said I, drawing a chair close to mine, 'sit down, please, I want to chat with you. So you are a country boy?'

"Glancing suspiciously at me, he answered, 'Yes, sir.'

"'Good,' said I cordially. 'I am always glad to meet country boys.

'I was born and brought up on a farm, and I know the work from the milking and chores before breakfast to milking and chores after supper. How old are you?'

"'Fifteen,' he answered, with some show of interest.

"'I as sixteen when I took this motto:

"'Work with all your might for what is right;
Work the best you can for God and man!'

and all that I did was with one aim. Shall I tell you that aim?' I asked.

"'Yes, sir,' he replied; and, Wintersvale, there really was not one trace of dullness in the eyes that met mine!

"'It was,' I continued, 'to do everything better than anyone else could do it! Are you to stay in Northville?" I asked.

"'I dunno,' he answered, more from force of habit, I thought. 'Father had a farm. The forest fires burned us out last month, so we came here because he got a job as fireman in the rubber-works.'

"'Do you like it here?'

"'I don't like the boys," he replied. They call me—Death—and—and—

"'And what?' I asked gently, for his lip quivered as he hesitated.

"'They call me stupid!' the poor fellow answered despairingly.

"'I laughed outright. 'Dittman, said I, 'they used to call me stupid, too!

"Not a word did Dittman utter, but his smile spoke volumes. Then I changed my tactics, and asked:

"'What do you aspire to, Dittman?'

"'I dunno. Nothin'. I guess. It ain't the boys alone; everybody calls me a poor stick!'

"'Come,' said I, 'don't mind what anybody says! Have an object in life, and, despite everything, go ahead! My object was to become a teacher. I attained my object. Every living boy, deep down in his heart, aspires to something. Now, Dittman, tell me what you would like to be ,as a man, you know."

"'A fireman,' he finally answered.

"'Like your father?' I asked, somewhat disappointed.

"'No, sir. A real fireman—a fire-fighter—and where, sometimes, maybe, you can save a couple of people from burning up!' and his words came with some spirit. I grasped his hand and said, 'Nobly spoken! Dittman; that is something to strive for, and I will help you attain it!" I then impressed upon him the necessity of an education. I spoke to him of the help his heavenly Father would give him and soon he was a new boy! I learned that he was fond of baseball, and then I want with him to Miss Turner's room.

"'Boys,' I said on entering, 'I have a new mate for you—my friend, Mark Dittman. If your ball team wants a good substitute, call on Dittman, and if he does not make good in the field and meet the ball fair and hard three times in five when at bat, then say I am no judge of a ball player. I take it in all your sports you will find him so full of grit that he will soon earn the nickname, "Sandy." Who gives three cheers for our new scholar?' I asked, in closing; and, Ralph, those boys responded nobly, three times three, and a tiger!

"I so arranged matters with Miss Turner that Dittman did not recite orally for a time, nor did any classmate have knowledge respecting his work. After school each afternoon I ferried him along, noting with delight the daily development. It was wonderful! Then, too, in school athletics, he made good my prophecy. He was imbued with one spirit—to do everything better than any other boy could do it, and his nickname 'Death,' was soon lost in the well-earned 'Sandy.'

"Beside all this a greater reward awaited me. He was a born leader. He hadn't been in the school many weeks before he had organized the boys in the upper classes into a fire brigade, his own idea. The lads were fairly wild over it, and their practice work was so interesting and exciting that soon not a boy in school but was eager to belong. Why, they even had a 'pony' company of fourth reader youngsters. All worked with a vim, and the exercise and recreation which it furnished proved of great benefit

to them in their physical development.

"This was fifteen years ago, you know, Ralph; and in those days Northville had neither fire engines nor professional fire fighters—our fire department consisting of some fifty or more call men, a few antiquated hand tubs and a ladder wagon. So the parents nodded approvingly at the idea of a boys' fire brigade, and, therefore, the school committee erected on the school grounds a three-story drill tower, the lower floor of which was used for the storage of the boys' fire apparatus—a few short ladders, fire belts, guns, harnesses, nets and such; and as some enthusiastic professional from the Centerville fire department was always on hand on drill days to show the boys the then up-to-date methods of battling with flames, it was wonderful how quickly the boys became quite proficient in the use of their various apparatus.

"I had early seen the advantages accruing from a knowledge of fire fighting, and had encouraged the boys to the extent of several times—on warm days—during that winter, letting the entire school take part in the fire-net drill. With a proper grip on the steel rims of the nest—a skill acquired only by practice—I had Dittman have the net squad stand under the different windows of our lower floor, and our girls and even the teachers were also taught how to jump into the net in such a manner as to alight on their feet. This may seem simple, but it is really, even for a boy, a difficult task to perform.

"Well, Ralph, now about my reward.

"It was an intensely cold morning late in March. Our school building was a three-story, flat-roofed, wooden structure, the two lower floors being divided into our eight schoolrooms, the third floor being used by our militia company as an armory.

"On the morning mentioned, our janitor had got in early, and by school time had the building comfortably warm for us. Then, leaving his furnace drafts wide open, he went to breakfast. His furnace probably got overheated. I was rummaging in our stockroom on the third floor, and intent on my search for a certain book I required, I noticed nothing unusual until I smelled smoke. I rushed into the hallway to investigate, when my worst fears were realized.

Not only was our building afire, Ralph, but a seething mass of flame was sweeping up the stairway. There was no escape for me in that direction, so I dashed up the belfry stairs, and, although nearly stifled by smoke, I pulled the bellrope with a fervor that made the old bell arouse all Northville; but of what avail? The Centerville railroad company had hired all our available horses to use in carting away the snow in the streets, and so the 'Northville fire department' was unable to bring their tubs and ladder-wagon!

"That was the lesson, Ralph, which gave this section a modern fire department.

"It seems some one of the teachers first discovered the fire; it was then confined to the basement, and, believing the boys' brigade capable of coping with it, she quietly summoned Mark Dittman, whom the squad has chosen their chief. Here the leadership in that boy asserted itself. He summoned his brigade, sounded the dismissal signal and got to work. But the fire was under great headway, and almost before the primary class had marched out, escape by the front door was cut off by the flames. The rear door led to the basement; and right here, Ralph, the net squad of the boys' fire brigade did yeoman service. All had confidence in the boys, and, although the jumping was now from the second story windows, there was no confusion. Not a life was lost!—not one!

"I was quickly driven by flames and smoke to seek safety on the roof. There was no visible means of descent, so I went to the side of the building not yet enveloped in smoke and gazed upon a scene I shall never forget, for the youthful fire laddies were already at work, and I witnessed scores leaping into the nets; so to attract attention to myself and my plight, I tossed my cuffs, one after the other, down into the crowd of boys.

"A cheer such as only school boys can give rose above the roar and crackling of the flames, and one boy came running toward the building. By using his scaling ladder, he climbed up the side of that building. As the teeth of the huge steel hook of the ladder caught into the gutter, I leaned over to assist my rescuer. It was Dittman.

"'I'm all right, sir!' he called to me, from where he stood on the window sill below, and the next moment he was on the roof.

"'Turn about is fair play, Mr. Blackman!" he called cheerily. 'You helped me; now it is my turn.'

"Over his shoulder was a long coil of rope, and as he quickly fastened one end of this around the base of the chimney for an anchorage, I heard him mutter firmly:

"'Work with all your might for what is right;
Work the best you can, for God and man!'

My own life motto—God bless him!

"He turned to me, as with a snap he fastened the other end of the life line to the belt around his waist. 'There's no danger to you, sir. Hang on to me, and, God helping me, I'll do the rest!' He tossed the slack rope toward the ground, and then the great fellow gathered me under one arm. A fervent inward prayer on my part, a slide off that roof, a dangling in mid air, and then, unharmed, I stood on the ground! It was a daring piece of work, and close indeed had been my escape from a horrible death, for soon the entire building was a mass of ruins.

"Now, why am I so happy this morning?' continued the old schoolmaster, as, wiping the tears from his eyes, he drew from his pocket a leather bill book. "Read this. All but the first part of my story you may give to your News. Ralph, I have said, 'Each life has moments that are never forgot.' I never forget my first meeting with—— But read this, the grand climax, as it were. Where is the dull boy, eh?"

"I took the telegram addressed him from a great western city. It read:

"Just appointed chief of fire department. Your motto always spurs.

DITTMAN."

—Epworth Herald.

JOHNNY'S GUN.

Johnny had a little gun,
Its voice was loud and strong,
It went off very suddenly
And Johnny went along.

Cookery Recipes

Cucumber Pickle—A reader who receives help from the Cultivator, reciprocates by sending in another cucumber pickle recipe. She has used it for years and it is entirely satisfactory: 2 qts. water, ½ teacup salt. Boil. Pour over 1 gallon pickles. Stand 24 hours. Rinse in fresh water and drain; put in kettle and boil 5 minutes or till all are scalded in a weak vinegar; skim out into cans or crocks and cover with a strong vinegar in which has been boiled ½ cup sugar, ½ tablespoon ginger, a few little onions and three or four little peppers, ½ teacup horseradish root cut fine, ½ teaspoon tumeric; pour over pickles while still boiling and seal. A little alum will serve to make them hard.—Mrs. G.

* * *

Cheese Omelet.—Two eggs, one tablespoons melted butter, one tablespoon grated cheese, two tablespoons water, seasoning. Beat the eggs, add water and seasoning. Melt butter in omelet pan, cook eggs till firm, fold and sprinkle with grated cheese.

* * *

Cream Waffles.—Put into a bowl two cups of sifted flour, three and a half level teaspoons of baking powder and half a teaspoon of salt. Beat the yolks of two eggs and add to them one and one-quarter cups of milk and then the flour mixture. Beat until smooth one teaspoon of melted butter and the whites of two eggs whipped stiff. Cook on a hot, greased waffle iron and serve with maple syrup. The waffles should be thin and crisp.

* * *

Breakfast Puffs.—Mix half a cup of water with half a cup of milk. Pour this gradually over one cup of flour, adding a pinch of salt. Beat until smooth, then add one stiffly whipped egg. Fill hissing hot, greased gem pans two-thirds full of the batter and bake thirty-five minutes in a quick oven.

* * *

German Puffs.—Cream one-half cup of butter, add gradually one cup of fine granulated sugar, then the yolks of three eggs unbeaten. Beat the mixture until very light and frothy; now add one cup of milk and two cups of flour, into which two level teaspoons of baking powder have been sifted. Bake in well buttered hot roll pans about twenty minutes. Serve as soon as taken from the oven, with foamy fruit sauce.

* * *

Date Gems.—One cup chopped dates, one-third cup butter, one egg, pinch of salt, two cups of flour, one cup of milk, two teaspoons baking powder. Sift together the flour, salt and baking powder, rub in the butter and dates, mix these in well, and make to a batter with the egg and milk. Bake in hot, well greased gem pans in a quick oven.

"It's funny," said the little pig,
"They didn't build me right,
And make my stomach just as big
As is my appetite."

A GOOD JELLY BAG HANGER.

Editor Cultivator: A hint to the housekeeper: Take two pieces of pine one by two inches, one being about eighteen inches long, and the other twelve. Bore a half inch hole about an inch from one end of long piece (this for the purpose of hanging on a nail), then nail the end of short piece to middle of long piece at right angles, using slender nails (No. 6 finish or box) so as not to split the end. Then take a piece of heavy iron wire (about ¼ inch) 22 or 23 inches long, and bend an inch of one end to slight angle and fasten to top of long stick with staple, bring down to end of short stick and fasten with staple or small nails, and then make a hook with rest of wire. Hang on a nail over sink or kitchen table. This beats a broomstick and two chairs all hollow. —C. S., Fullerton.

Another hint for the same purpose is to take the socket of the ordinary cheap bracket lamp for a basis of a strainer holder. If handy screw on wall near sink or near where wanted. If not, screw on board in which is hole for hanging. Then take strong iron rod, say quarter inch, or as large as the socket of the bracket will take in, and bend at an angle, either right angle or acute. The end which goes in socket, say, an inch long, the other twelve or more inches, as may be desired, with a bend-up for hook at lower end.

HOMELY HINTS.

For a burn take the white of an egg. By excluding all air and forming a covering over the burn the pain is instantly relieved.

ABOUT ANTS

Around chicken coops, barns and other outhouses, ants may be a positive pest. A bottle of K.A.P. means extermination Sent prepaid, by express, only, 40 cents.

When writing advertisers mention Cultivator.

Tender feet should be bathed in alum water. If colored hosiery is worn have the soles and heels white. Tender feet are made more sensitive by the dyes used in the stockings.

After exercising or bathing when the pores are open and the skin is in a glow, do not rush out into the open air or into sudden changes of temperature.

When vegetables cook dry and scorch or burn set the vessel at once in a little cold water, and they will taste very little, if any, of the scorching.

To clarify strong lard or butter, heat it and cook in it a sliced raw potato.

A GOOD GARDEN.

The pleasures from a good garden can hardly be estimated whether it be of vegetables or flowers. We wish more of Cultivator homekeepers would give their experience with the garden. It may be remembered that "Rebecca" wrote for some information some months ago and confessed to perfect ignorance of California conditions, being a Simon-pure "tenderfoot." But open eyes and nimble fingers have accomplished much since then in the garden. Note the following record of progress:

Dear Cultivator: Do let me say dear! for you have surely been a friend to the cultivator of this little ranch since last November, when my subscription commenced. This little ranch, which you dubbed "The Tenderfoot," is getting prettier every day, thanks to your many kindly advices. If I am in a quandary, and I am in many, I just wait until Saturday comes, and with it my paper, and I am sure to find in its columns a solution to my difficulties.

Last week I was wondering how to treat my chrysanthemums, when your suggestions came. Just what I wanted. Now I was thinking over my vines, which are just as luxuriant, and here comes all your good advice along that line. Do you wonder that I want to say dear? My only trouble is, with all your good suggestions, I just want to work myself to death, and make everything more beautiful every day. Not one cent has been paid for our vegetables since March. Strawberries planted in January have given us fruit steadily until now I am forcing a rest by withdrawal of water. My blackberries, Loganberries and raspberries are making pretty, green trellises. Next year I suppose they will give us fruit. The fruit trees of every kind have doubled their height in this first season, and I just look at them all in admiration.

You say, "will, work and water" will accomplish anything in California, and I am sure it will form my experience of this year.

I am busy putting away a long string of onions, dried okra, beans of several kinds, and many gallons of cucumber pickles. The tomatoes will be canned as they grow more abundant. All of these from our garden, and ducks, chickens (and I am sorry I can't say turkeys, but they have gone to a better land, save one, which we are counting on for a Christmas dinner). I am sure we are not ashamed a little bit of our "tenderfoot" farm.

I have rejoiced in sending several baskets of lovely vegetables to my neighbors and must confess to a broad smile of satisfaction as they praised them. I always say to them you may thank the California Cultivator for never was there a greener mortal than yours humbly at the beginning of this year.

Don't think for one moment that our thoughts all go to the eating question alone, for our flowers are simply wonderful in their growth and luxuriant bearing. I am busy saving seeds of all kinds for larger ventures another year, and know you will send me your good wishes for success.—Rebecca, Pasadena.

Surely the good wishes always; but, better, in this case, congratulations.

Los Angeles Markets.

Los Angeles, August 16, 1905.

Butter.

B. of T. Creamery	57½
Valley Creamery, fancy	55@57½
Coast Creamery	47½@50

California Anchor	13¼
Northern	12½@13
Eastern	16
Domestic Swiss	16½
Imported do	27½

Eggs.

Eggs are slightly firmer and higher quotations than last week by a fraction of a cent a pound. Receipts are somewhat lighter.

Eggs, fresh ranch	29@30
Eastern and Storage	25@26
Seconds	21@22

Poultry.

Poultry is considerably stronger and slightly higher quotations all along the line. Turkeys, live, are still quoted at sixteen and eighteen cents, though offers for dressed stock are freely made at twenty-three and a half to twenty-four. The live stock coming in at this time is said to be very light, requiring fattening before up to the demands of this market.

Fryers, 2½ lbs	13@14
Broilers, under 2 lbs, per lb	13@14
Young Roosters, per lb	13@14
Hens, per lb	12

Cows, cwt	3.00
Calves, cwt	4.75
Sheep, ewes, per head	3.50
Lambs, do	3.00
Wethers, per head	4.00

Potatoes.

Potatoes are still firmer, though northerns are quoted at the same price as last week. Large quantities of fine stock have been received from the north and the better grade of locals are being offered, but with it all quotations on locals are much higher than last week.

Northern, per ctl	1.25
Locals, per ctl	75@$1.25
Sweets, white, per cwt	$2.50
Sweets, yellow	$2.50

Vegetables.

The only feature in the vegetable market is in a big increase in summer squash, which have been increased to twenty-five and forty cents. Cucumbers are also much higher, ranging now from thirty to forty cents. Cabbages are almost out of the market and will command today double last week's price, if they can be had. One dealer said that seventy-five cents would be quickly offered, if a load should come in. Tomatoes show a wide range of values, running from fifteen cents to fifty cents and even higher. Some very nice stock is being offered which is commanding the top quotation.

Raspberries—Per chest, $6@9.

Strawberries—Per chest, Longworths, $6@8; large varieties, $3.50@5.50.

Huckleberries—Per lb., 6@8c.

Vegetables.

VEGETABLES—Tomatoes, per box, 35@65c; Green Peppers, per box, Chile 35@65c; do, Bell, 40@75c; Okra, per box, 75@90c; Garden Beans, per lb., Green, 1½@3½c; do, Wax, 2@3c; Lima, 8@9c; Garden Peas, per lb., 3@4c; Cucumbers, per box, 20@35c;

Summer Squash, per box, 25@40c; Egg Plant, per box, 50@75c; Garlic, per lb., 5c; Green Corn, per sk, 50c@$1.25; per crate, $1@1.50.

ONIONS—Per sk, Yellow, 70@90c.

Dried Fruits.

General market for dried fruits is very strong. Both prunes and apricots claim the principal interest. Prunes are strong with growers demanding three and three-quarters cent basis throughout the Santa Clara valley.

DRIED FRUITS—Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb, as follows:

Apples—Evaporated, 1905 crop, fancy, 7½c; choice, 6¾@7c; standard, 6¼@6½c; Sun Dried, nominal.

Peaches—1905 crop—Crawford, fancy, 8½@8¾c; choice, 7½@8c; standard, 7¼@7½c; Muirs, fancy, 8¾@9c; choice, 7¾@8½c; standard, 7½@7¾c.

Prunes, 1905 crop—Sack basis, f. o. b., for boxed goods add ¼@½c; four-size basis, 3¼@3¾c; old crop, 2¾@3c.

Apricots—1905 crop—Royal, fancy, 8¼@8¾c; choice, 6¾@8c; standard, 6¼@6¾c; Moorpark, fancy, 12c; choice, 8@9½c.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c; choice, 3¼c; standard, 2¾c; ungraded, 3½c.

Honey and Beeswax.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

Hops.

The price of desirable old crop is nominal at 15@20c per lb., according to quality, new, 1905 crop, 14@16c.

Beans and Seeds.

BEANS—Prices per ctl. for sound selections; Large White, $2.75@2.90; small do, $3.50@3.75; Pea, $3.25; Limas, $5.50@5.75; Red, $6.50@8; Pink, fancy, $3.65@3.90; recleaned, ordinary to choice, $2@2.50; Bayos, $4@4.50; Blackeyes, $3@3.25; Red Kidneys, $4@4.50; Rain damaged lots of all descriptions offering from 50c@$2 a ctl below foregoing figures, according to condition.

Live Stock.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@5½c; rough heavy, 4¼@4½c; common, 3½@4c.

Hay and Feedstuffs.

HAY—Per ton: Wheat, $7.50@13.50; Wheat and Oat, $7@12.50; Oat, $6@11; Barley, $6@9; Clover, $7@10; Alfalfa, $6@9; Stock, $5@6.

New Crop—Wheat, $9@13.50; Oat, $7@11; Wheat nad Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $21.50@22.50.

COCOANUT CAKE—In lots of 10 tons. $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@28.50.

Flour and Cereals.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.35@$1.42½ for new crop; old higher; White Milling, good to choice, $1.45@1.55 for new and $1.60@1.65 for old.

BARLEY—Choice, No. 1 Feed, $1@1.05; some fancy up to $1.06¼; off grades, 97½@98¾c; Shipping and Brewing, $1.05@1.10; Chevalier, $1.10@1.25.

OATS—Good to choice White, nominal; Red, $1.20@1.40 for new crop; Black, for seed, $1.40.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.40@1.45; small do, $1.55@1.62½; White, $1.37½@1.42½; Eastern, Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.40.

RYE—Good to choice, per ctl., nominal; new, $1.47½@1.50.

CITRUS MARKETS

The shipments of citrus fruits from Southern California show that the season is nearly over. Up to date there have been nearly 28,650 cars of oranges and lemons sent out. Of this number, about 2700 cars were lemons. The shipment of fruit consists of about twenty cars of oranges daily and from five to fifteen cars of lemons. The large amount of lemons which have been held in the packing houses for the higher prices have all been cleaned up, the shipments now being sold as they are picked from the trees, and are sent out as quickly as they can be cured. Not for many years has the lemon grower received as good returns as he has during the last two months. The returns on Valencias and Mediterranean Sweets have also helped to raise the average prices for the season on oranges. The prospects are that the market will hold up as long as the hot weather in the East continues and allow all the remaining fruit in the State to be shipped out at remunerative prices.

New York.

Sales of California fruits in the New York market Monday were very light, only three cars of oranges and two cars of lemons having been sold. Judging from the active demand at the sales, stocks must be getting pretty low. The markets were active and prices a shade higher, fancy grades of Valencias ranging in price from $4.85 to $6.60. Choice grades brought from $4.25 to $6.30, the higher prices being for stock in good condition and packed strictly up to grade. One car of choice lemons in good condition averaged $5.27 per box, which showed the strength of the market.

On Tuesday five cars, consisting chiefly of Valencias, were sold at auction. Extra fancy fruit sold as high as $6.60 per box, the choice grades bringing $4.40 to $5.80. St. Michaels found ready sale, fancy bringing an average of $5.25 per box. Fancy grapefruit brought $5.30 per box.

On this day 28,000 boxes of Sicily lemons were sold, the market being strong on that variety. Prices ranged for fancy 300s $5.85 to $6.50; choice 300s, $5.50 to $6.00; fancy 360s, $5.75 to $6.20; choice 360s, $5.10 to $5.85.

Four cars of oranges and one of lemons were sold at auction Wednesday. Prices ruled very firm. However, some brands did not command as high prices as formerly, but results were satisfactory.

Boston.

The Boston market has held up fully as well as that of New York. On Monday, five cars were sold, orchard run Valencias realizing an average of $4.80 per box. Standards, lemons, brought as high as $4.85. Choice grapefruit sold up to $5.85.

On Tuesday there were but two cars of fruit offered, one of Valencias, the other of lemons. Extra fancy Valencias sold at an average of $5.50 per box. Extra choice brought $5.35. Choice lemons sold for $4.60.

California oranges took another advance Wednesday, carrying prices up as high as $6.05 per box for choice Valencias.

Philadelphia.

The Philadelphia market remains steady and firm on good stock. On Monday two cars of lemons were sold the choice grade realizing $4.80 per box, while the standards brought $3.90, the later being in poor condition.

Chicago.

The demand is very good. Offerings moderate. Lemons ruling very firm. Late Valencias, extra fancys, brought $5.00 to $5.25 per box. Small sizes, twenty-five per cent discount. Grapefruit sold for $2.75 to $3.00.

Lemons were firm but demand not very strong. California fancys, 300 to the box, brought $6.50 to $7.50; 360s brought $6.50 to $7.50; larger sizes sold at from thirty-five to seventy-five cents discount. Not many oranges were offered. Late Valencias brought $4.50 to $5 for regular sizes and fancys brought as high as $5.25. Grapefruit, $2.75 to $3.00.

THE AQUARIUM.

The aquarium introduces us to new scenes, hitherto hidden from our view, makes us acquainted with the economy of creatures of whose very existence many of us, not altogether unlearned in the history of the world, were previously ignorant. Their habits of feeding, of moving, and burrowing; their battles, their changes of form, the display of even a strange intelligence, working its way by wonderful means to wonderful ends, impress the observer with an idea of the boundlessness, the variety, the adaptations and resources of a world brimming with life, in all manner of strange forms and developments. Here we see them equipped and armed for battle against each other, the strong destroying the weak, yet each contributing its part to the preservation of the whole, just as in all other departments of nature the great balance of perfection is sustained by incessant and intestine war; the struggles of opposing elements, and powers, and beings, all working mysteriously in a manner independent of isolated circumstances—nature, the prodigal mother, setting no value upon individuals, but regarding tribes and races as paramount, the whole seeming confusion tending to one great end—the revolution of the mighty wheel on which the creatures are painted as signs, and in which ages are but minutes in a revolution which itself is eternity.

The Southern California Fruit Exchange announces that it will soon establish a selling agency in London. London now uses about 750 cars of oranges weekly, mostly from the Mediterranean.

The exports of butter from Humboldt county for the first six months of 1905 was 131,348 pounds heavier than for the same period of last year. The increase in value was $34,348.

The lemon growers of Whittier netted $2.30 per box for June shipments. For July and August the price is expected to go even better.

IN WOMAN'S BREAST

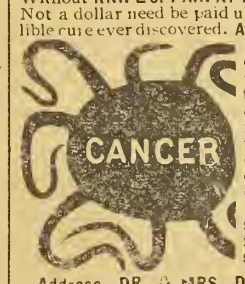
ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

THREE PHYSICIANS OFFER $1000

If They Fail to Cure Any Cancer

Without KNIFE or PAIN AT HALF PRICE for 30 days. Not a dollar need be paid until cured. Only infallible cure ever discovered. ABSOLUTE GUARANTEE.



Best book on cancers ever printed, Sent FREE with testimonials of thousands cured without a failure. A Pacific island plant makes the cures. Most wonderful discovery on earth. Small cancers cured at your home. No X-Ray or other swindle. Write today for our 130-page book, sent free.

THE THOMPSON SEEDLESS GRAPE.

By courtesy of Geo. C. Roeding we print above a cut showing the bearing qualities and habit of growth of the Thompson Seedless. This grape is identical with the Seedless Sultanas of Asia Minor, and has proven very popular in California. It is a very early shipper, its raisins are of superior quality, and as a sherry grape is well liked.

CIRCULATION EXCEEDING 10,500

THE MAKING of a SUCCESSFUL POULTRY FEED

Part view of the manufacturing department where Coulson's Egg Food and Coulson's Chick Food are made. Notice solid stone floor. See the men at work bringing the different feeds and ingredients to the mixing machine. Thousands of sacks are handled daily. There is one pile containing over a thousand sacks of Armour's Meat Meal. Another pile of sacks of fine ground Bone Meal. Another pile of three thousand sacks of shorts. Another of fifteen hundred sacks of flour middlings. In another place you will notice a carload of Armour's Dried Blood. In another, eight hundred sacks of fine ground beef scraps. In another pile a carload of ground oats, and in another a stack of two cars of granulated corn meal, and back in the corner sixty thousand pounds of Minnesota Millet Seed, car lots of Cracked Rice, steel cut Oat Meal, different seeds, etc. There are tons of charred bone Charcoal, and barrels of powdered Willow Charcoal, and big stacks of many other ingredients.

OUR SPECIALTY—MAKING GOOD FEED.

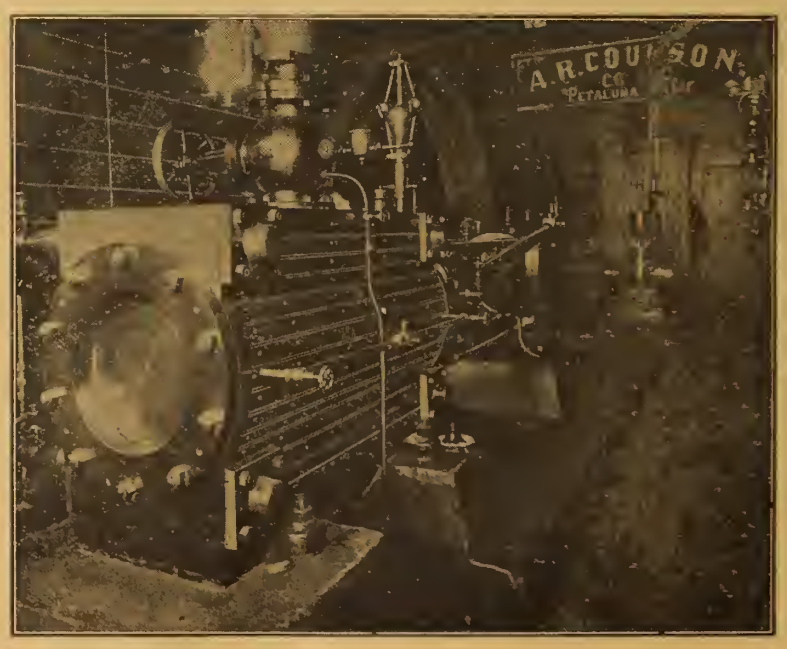
John D. Rockefeller's specialty is oil, Andrew Carnegie's, steel; Senator Clark's mining. These men were and are specialists. They organized themselves to excel, just as we have organized ourselves to excel in the manufacture of the BEST FEED for POULTRY. It is the one thing we think of, dream of, and talk of. When a man's heart is set on his task, he does it better than the "don't care fellow."

We do not and will not employ any one who is not interested in their work, consequently we repeat to you that we make GOOD FEED FOR POULTRY, (none better but lots that are worse, we assure you.) Making GOOD FEED for poultry is our specialty, and we have got it down to perfection. We manufacture a feed that will make your hens lay, as you never dreamed of before. Not only is the feed good to make hens lay, but it helps the fowls and it also gives them richer blood and keeps them in healthier conditions.

Being specialists in the line of mixed poultry feed, we can give you the best feed at the lowest prices.

All fowls over two months old, pullets and laying hens should have one meal a day of Coulson's Egg Food as a warm mash. Feed it for one year and see what there is in it.

It takes several weeks to show any great gain in egg production on any change of feed. Many poultrymen have tried Coulson's Egg Food for a few days and given it up as a failure, while there are hundreds and even thousands of poultry keepers who have fed Coulson's Egg Food for over a year's time and have made the greatest of success, and who feed Coulson's Egg Food every day to their hens, and every day they get plenty of eggs.



TWO HUNDRED HORSE-POWER ENGINE.

That runs the machinery which grinds up the bones for making fine ground bone meal, and pulverizes the charred bones for making Bone Charcoal, Etc.

These ingredients are used in making Coulson's Egg Food (a mixed food for pullets and laying hens) and Coulson's Chick Food, which are mixed by machinery and mixed properly.

The healthiest looking fowls, with bright red combs, are those that are fed on Coulson's Egg Food.

TRY IT FOR ONE YEAR.

Experience, backed by the general law of average, proves that feeding any change of food for the first week or two doesn't bring results. A trial of a SACK OR TWO is a waste of money. If you GO IN, stay in, and it WILL PAY YOU. "Keeping everlastingly at it" is the ONLY WAY TO SUCCESS.

MR. POULTRYMAN, there is only one way to buy, and that is on record of WHAT YOU WANT. If you want to make a good record, buy good feed. Character is a man's record. So it is with feed. Buy on character. When you buy Coulson's poultry foods you buy on character, and get a standard article of feed that contains only the best and wholesome ingredients.

Rumsey, Cal., Dec. 15, 1904.

This is the first season I have used Coulson's Egg Food and I find it excellent for the purpose. Since feeding it I have had more than double the number of eggs that I ever have had before from the same number of hens.

Yours truly,
A. A. HENRY, Rumsey, Cal.

Experiment in Incubating Resistant Grafts

An Original Method Pursued by Dr. W. N. Sherman, Fresno, Cal.

One of the important questions be-re the vineyardists of Northern and entral California, is to successfully eet the encroachment of the Phyllox-a. The experiments carried out in rance and Spain have proven valu-ble. At the present time no one ems to have solved the problem ful-. We know that several of the resist-it stocks have been tried and proven tisfactory in various soils, and with niferra grafts. A recent letter from of. Bioletti, told how successful me of the vineyardists of France had en with Rupestris and the several brids of Rupestris and Riparia. One portant matter relates to the suitable sistant stock for the several varie-es of table grapes, so successfully own in California, and also of the rai-n grape. In Fresno county, for sev-al years past, the larger vinyardists ve been experimenting with resist-it stocks, most of them in a small ay, but some of them boldly planting it large vineyards.

The important experiments made in rance with the wine grape on resist-it stocks and their brilliant success. observed and recorded by Prof. Bio-tti, would seem to settle the matter. his, however, is not the case with the her varieties, and the ones that inter-t some of us most. There seems to no settled opinion, or proven ex-rience, as to what resistant stock is st suited to the several varieties of ble and raisin grapes. The success tained with the several favorite ocks for the wine grape, has in-enced others in using them for the ble grape, where the soil and cli-atic conditions seemed favorable, but yet no definite results have been an-unced.

Many of the farmers of this part of e State are indifferent about this estion and continue to plant vine-ards as heretofore. Many do not exer-se ordinary care in disinfecting their ttings from vines that are likely to infected. Their argument is that e phylloxera works so slowly in our t sandy soils that it may be years fore their vines are appreciably in-red, and that they can secure profit om their plantings for a sufficient riod before any damage may be done. here is some reason in this argument, r we know of vineyards that have en infected for ten years, and are ill profitable, yet far from their orig-al vigor and productiveness. About ur years ago the writer began plant-ing vineyards on resistant stock, in an-ticipation that a time might come when the old vineyards would suffer and on the theory that it is not wise policy to plant new vineyards in in-fected districts unless they are on resistant roots. The old method of bench grafting rooted cuttings, and grafting in the field were both used with fair success. The injury resulting from carelessness in cultivating and plowing, and the continued working over of the vines that missed, proved expensive and slow, and we abandon-ed these methods for the newer ones, namely, grafting the resistant cuttings and healing or callousing them in, in dry sand beds or an incubator. We now have Emperors and Thompson Seed-less, grafted on Rupestris St. George, that are three years old and in bear-ing this year. They are not unlike

Photograph of Vines Taken July 10th.

in vigor and size, the same varieties on their own roots, in the same soil. We have great hopes for their success, for we see no good reason why these varieties should not take as kindly to the resistant Rupestris as the several varieties of the wine grape have done.

We admit that the time has not yet come, when we can speak positively about this matter, but so far as our experience and observation goes, we believe we are warranted in our hopes. The Rupestris St. George has been used quite extensively in this neighbor-hood, and the hybrids 3306 and 3309 to some extent.

The method of grafting the resistant cuttings, callousing them in sand beds or an incubator, and planting in nur-sery rows, is preferable to the older methods of bench or field grafting the resistant rooted stock. Last winter while grafting cuttings in the usual way, for callousing in sand beds, I had the foreman put some of these grafts in the olive oil cellar, where I had a large box stove constantly heat-ed, and try the incubating method. At the time I was unable to find the re-print of Prof. Twight, giving full de-tails of the French methods, so I sub-stituted my own plans, as follows: The grafted cuttings were carefully ar-ranged in moist moss and placed in layers, each layer covered with moss an inch thick. Fruit picking boxes holding fifty pounds, were used for the purpose, and the root end of the cut-tings were laid to the outside so that the grafted ends were in the middle of the box. These boxes when full held about one hundred and fifty cuttings. No charcoal was used and the boxes were placed one on top of the other, three high in this cellar, where we were making olive oil. At night the fire was renewed so as to maintain the tempera-ture. The temperature ranged from seventy to eighty-four degrees. After ten days, the top layer of moss began to dry and was moistened by a light sprinkling of water. The under layers were not disturbed, and the moistening was made but once while they remain-ed in the cellar. Callousing began within two weeks and continued rapid-ly. Cuttings were removed directly from the cellar to the nursery and planted, without subjecting to sub-dued light.

The grafting was done from the 12th to the 30th of February, and the cut-tings were planted in the nursery dur-ing the first week in April. At this time the cuttings were all well calloused and many of them were both sprouted and rooted, that is, the scion was sprouted, two or three inches long, and some of the cuttings had started to root. Most of them grew rapidly, and at this writing we estimate ninety per cent of strong, healthy, vigorous vines with canes from two to two and one-half feet long. Very few of the scions rooted, as in the case with other methods and the results we obtained were a great surprise. The cuttings used were made about ten days after the first heavy frost, likewise the scions, which were originally meant for planting as cuttings, and not intended for scions. All buds were removed from the resistant cuttings before they were grafted.

About two thousand cuttings were grafted and treated this way. No spe-cial care was used to graft these better than the others, and the same stocks were used as with the ones we made and calloused in the sand beds. Unfor-tunately the grafts treated in the sand beds were badly damaged by the March frost, and we estimate sixty per cent of these are growing and a large proportion of them, the scions have rooted. Of the vines treated by the incubation method, we have made pho-tographs so as to show the rows length-ways. The cuttings were set about six inches apart in the nursery rows, and at the time the picture was made the vines were so vigorous in canes and foliage, that the picture does not give an adequate idea of them.

All the cuttings treated by this meth-od were grafted to Malagas, and while we would not draw a conclusion from one experiment, the results were so re-markable that we shall follow up the method and hope to report as good or better results. We hoped to make an earlier report of this experiment, but all the knowing ones advised us to wait till the vines attained a greater age when my results would be differ-ent. As all these cuttings are now large, vigorous, healthy vines, show-ing the Malaga foliage and appearance, and as several people have viewed them critically, the writer has no fear of these recorded results being doubt-ed.—Dr. W. N. Sherman, Fresno.

Missouri is the first poultry State in the Union. More than 155,000,000 eggs were produced in the State in the last year. The surplus products of the poultry interest now exceed by $2,-000,000 the value of mules shipped out of the State. The estimate does not in-clude the enormous consumption of eggs at home, but only those actually sold.

California Horticulturally

By John Isaac, Sacramento, Cal.

THE MEXICAN ORANGE MAGGOT.

There are two causes for satisfaction to our orange growers resulting from the late investigation into the orange maggot in Mexico, carried on under instructions from the Commission of Horticulture. The first is, that so far this pest is confined to the tropical portions of our sister republic, the center of infestation being in the State of Morelos, from which place it takes its common name, and spreading from there to Vera Cruz, Guerrero, Oaxaca and other States located in the tropical portions of the country. While maggoty oranges have been found in the northern States of Mexico, these have not been grown there, but have been imported from the tropics in the early part of the season, and before the fruit on the high tablelands ripened. So far, the orange maggot has not been found in any oranges grown in Sonora, Chihuahua or other States bordering on our own country. This makes the danger of introducing the pest more remote, and while not altogether a surety against its arrival in our State, at least reduces the chances to a minimum.

The second satisfactory feature is that the Mexican government, spurred to action by the embargo placed upon their fruit by the State Board of Horticulture, has taken in hand the extirpation of the pest, and is leaving nothing undone to prevent its spread beyond its present limits, and, so far as possible, to reduce it below the danger limit in those sections. To this end, means have been taken that even we in California should hesitate to try, the destruction of the whole fruit crop in the infested section, for instance, the steady employment of gangs of men for the purpose of gathering up the pupae and the capturing of the insect in every stage of its existence. These efforts, added to our own strict quarantine against fruit from the infested section, give assurance of safety to our orange growers from this pest.

It is claimed by the Mexican entomologists that the Trypeta ludens is purely a tropical insect and that it will not live in any section where a low temperature, as low as 37 degrees, is common. If this is true, it is another assurance of safety for us, at the same time it is not always safe to rely upon the inability of tropical insects to withstand the lower temperature of our own State, and, being out, it is much safer to keep out a pest than to admit it for experiment's sake and to prove a theory.

That the pest is not found in Northern Mexico is borne out by the present investigation and by others carried on by Dr. L. O. Howard and Prof. Albert Koebele, both of whom lend the authority of their assertion that the pest is as yet confined to the tropical portions of Mexico and especially to the State of Morelos. In this State, at Yautepec, is found the principal orange growing section of the republic, and here certainly its destructive work is sufficient to warrant California in taking every precaution to keep it from obtaining an entry over our borders. Here the fly attacks the orange at the ripening period, in October and November, laying a mass of eggs beneath the rind of the ripening fruit, and scarcely an orange or sweet lime is left unattacked. During the season when there are no ripening oranges, the pest turns its attention to the mango and guava and these fruits are as badly infested as the orange later on. So serious a pest is this fly that in the State of Morelos, where it is at its worst, it has rendered the growing of fruits which it attacks at least unprofitable. In a report to the government Prof. Herrera, the government entomologist, states that:

"In Cuernavaca hardly $1000 worth of mangoes can be gathered free from the pest, although the total production is at least five times that amount. The orange can not be grown here on account of the worms.

Mr. Guillermo Gandara informs us that in a great many of the orchards at Cuernavaca the plague has spread to such an extent that the owners have been compelled to discard the cultivation of mango trees, or if they desire this fruit they gather it when green and place it between plantain leaves to ripen. In this district in a few days Mr. de la Barreda collected and destroyed by burning between seven and eight thousand mangoes, all of which were infested. Professor Rangel removed over 3000 larvae from mangoes in Yautepec, and destroyed over 57,000 in which the worm was known to exist. According to a statement made at an assembly of agriculturists at Yautepec in February, 1900, the loss of fruit from this source alone in this district is from 33 to 40 per cent, or over $20,000.

Even these large losses will fall below the reality, for they do not include the fruit which drops from the tree during the year all through the State of Morelos."

It will be seen from this statement how serious a pest the orange maggot is where it has obtained a foothold, and while the past investigation may indicate that the danger of its introduction into California is perhaps not so serious as has been thought, it is still sufficient to warrant us in taking every precaution and to prevent us from taking any unnecessary chances.

* * *

GRAIN IN THE NORTHERN COUNTIES.

As harvest progresses in the counties of the San Joaquin and Sacramento valleys, it becomes more and more apparent that the grain crop will fall very much below early expectations, and these were not extravagant. The total output of wheat in California this season will be insufficient to supply the usual demands of our own State. In olden times large fleets of grain ships could be seen in San Francisco bay awaiting charters for cargoes of wheat to Europe and our annual export of grain was enormous. But, year by year, our exports have grown smaller, until at present the grain fleet in our waters is noticeable for its smallness. All sorts of reasons are adduced for this state of affairs, and also for the fact that our grain is not of as good quality as it used to be, but the truth can be probably found in the fact that for forty to fifty years past we have cropped the same land to grain, and have never returned to the soil any of the fertilizing elements which we have removed from it. In other words, our grain soil is exhausted. It is a question whether there was ever better wheat land than that of California in the early days. We can remember when wheat farmers would sow a crop one year, let it volnteer the second and sometimes even the third and so gather two or three crops from one sowing. Of course the second and third crops were not first class, but they paid well for harvesting. But those days are passed and California's prestige as a wheat State is gone, all that we may hope for now is that by deep plowing and fertilizing we may yet produce fair crops on some of our wheat lands.

* * *

A POOR FRUIT SEASON.

Fresh fruits in the northern counties have not turned out well as a rule this season. Apricots yielded a good crop, about the only fruit that did, but these were very much disfigured with the shot-hole fungus, which was worse than usual this year. Pears and peaches are very light crops. The theory is advanced, and seems the most plausible one, that the heavy rains which came at the time the pears and peaches were in bloom washed out the pollen and so prevented fertilization. This may also be the cause of the severe attack of shot-hole and other fungi, which are always worse in wet or damp weather.

* * *

THE COMING STATE FAIR.

The State fairs for some years past have been so severely criticized, and to a great extent justly so, that they have fallen into disrepute among the farmers, in whose interest they are supposed to be run. Gradually, year by year, the gambling fraternity have become stronger at these shows, until at last they were little more than horse races, run at the State expense for the benefit of gamblers, and the farmers were conspicuous by their absence. A determined effort is being made by the new management this year to reform this and the fair is to be a truly representative exhibit of the State's material industries in which horticulture and agriculture are to be given a conspicuous place. A number of counties have already expressed their determination to take part, and we look for the best and most representative agricultural exhibit seen in Sacramento in many years, and in which horse racing and the gambling fraternity will have to take a back seat.

In nearly all cases the best tools are the cheapest, and it pays better to buy good new ones than to worry along with poor, worn out ones.

BEEKEEPING FOR BEGINNERS.

The old adage that there is always room at the top applies to all departments of life and work. At this season of the year it is full of suggestion to the beekeeper in reference to

Marketing.—My father was a very thrifty farmer. As evidence of this he commenced with nothing and though he brought nothing to his aid except the business in hand, yet he acquired a large farm property. It was one of his rules to always market his farm products as soon as they were ready. He said that very likely he might often secure more by holding his wheat, wool, etc., yet he had noticed that, taking the years all in all, he was surely the winner who sent his products to market as soon as they were ready. There are various other considerations that add strength to this advice. Nearly all products, especially those of the farm, lose in value with age. Thus we may expect to meet the market in the best condition with wares sent out as soon as ready. We may also save much in the way of risk from fire and other losses. I believe that this advice from my father, like almost all of his suggestions, is well worth attention by us all.

In case of honey, the argument has certainly much force. People are ready for honey early in the year and expect it. Just at this season the appetite is whetted, the eye is alert and there will be sore disappointment if the best that the beekeeper can give is not on the counter of the groceryman at the very dawn of the season. In this product, as in others, the article in question is never so fine in appearance as it is just when it comes from the hive. The past year there have been several cases of fire and more than one of flood. Often. honey kept over one season was swept to ruin, whereas if the above suggestion had been heeded it would have brought good money in the market.

In case of comb honey, there is another very important reason why it should be sold as soon as ready for the market. Comb becomes brittle with cold, and thus there is always danger in shipping it after the warm weather is over. It is a very serious matter for the combs to break down, for there is very likely not only loss of the individual comb that has fallen, but often serious damage to the whole case. He who undertakes to ship comb honey, after the cold of winter has come upon us, is running a risk that no wise person would care to take. While I recognize the fact that occasionally it will pay to hold our goods for better price, he will be most fortunate who adopts the plan of always shipping his wares as soon as they are ready for the consumer.

* * *

Shipping Comb Honey.—Apropos to the above, a word is in order regarding the method of shipping comb honey. One of the reasons that comb honey is so attractive in the market comes from its beauty. We all know that to be beautiful it must be entirely free from damage. It will pay then to spare no pains in shipping our comb honey to protect against breaking or marring. It is best to ship in rather small cases; those holding either twelve pounds or surely not more than twenty-four. These should again be put in the shipping box, each box holding say twelve of the former and six of the latter size cases. Thus in either case each box will carry 144 lbs. It is well to put a little excelsior on the bottom of the box, to break the jar. Again, if the shipping box has not finger holes in the end, it is wise in nailing on the cover to let the center board, which should be an inch thick and four or five inches wide project over two or three inches for convenience in handling. On this board should be printed in large letters, "Beautiful Comb Honey. Handle With Care." There is one more thing which seems simple, but which is certainly worthy of attenttion. In putting our comb honey into the car, the frames should be run lengthwise as there is much less danger of breaking combs from the jar of coupling the cars.

* * *

RAISING STRAWBERRIES.

I have some friends at Owosso, Michigan, who have gained a very desirable reputation as producers of small fruits, especially strawberries. As we all know, this business is pretty strenuous and a portion of the year calls for hardest effort. The present season, owing to the great amount of rainfall, has been one of peculiar difficulty. I reached my friends just at the close of the season, and yet I found them very happy in their work, with no word at all of complaint. In questioning as to the cause of their good feeling, I found that a good thick pocketbook was the explanation. To show something of their success, although Owosso is a small town, less than twice the size of Pomona, yet one of my three friends marketed in the town one hundred and fifty bushels of strawberries in one day, and this notwithstanding the fact that he depends entirely on the local market. Here again, I wished for explanation. "We aim to produce a berry which people feel that they must have," was his reply, and does not this tell the story of success in almost every line of work. I asked, "How do you do it?" The answer was, "We set only very carefully selected plants, and that of only one of two of the best varieties," He said, "You remember when we were young, the Wilson was the rage. Today no one could succeed with the Wilson, even at its best." Again," said my friend, "we take great pains with our cultivation." I said, "Was that so necessary during this rainy year?" "Yes," he said, "very necessary, for this reason. We must have a gravelly or sandy loam. For the best success will come only from frequent cultivation." "But," said I, "do you not cultivate chiefly to conserve the moisture, and this year you say you have had a surplus of moisture the season through?" He replied, "We wish all the richness of our soil to go into our plants and berries, and so, either by mulch or cultivation, must keep the weeds down. But more than this, we must aerate the soil. I doubt if any of us fully appreciate the value that comes from our bacterial friends. They never do their best in a soggy soil."

These gentlemen are also very alive to the necessity of frequent and ample fertilization. They renew their field every two or at most three years. The first year they get only a partial crop. The second year they expect a great crop, and in case the vines maintain their vigor they leave them for a third year, when they often get a very respectable yield. In either case, they plow up as soon as the picking is over and sow to wheat, seeding also at the same time to clover. Thus we see that they practice the use of green fertilizer, for the clover, when it is at its best is plowed under and the ground again set to strawberries. In this last case, as they put in the clover they also put in a liberal supply of potash and treated bone meal. It may be that in California the potash might be omitted and we might have to put in some other legume in the place of the red clover. Cow peas, the vetch or peas would do well.

* * *

SECRETARY WILSON.

I am sure I am not alone in my deep regret at the onslaught that is being made in many quarters upon the Secretary of Agriculture. I do not believe that the farmer could have a better friend than he has in Secretary Wilson. It is easy to account for his wearied look, which he has carried in these days of cruel aspersions, for he ha the interests of our farmers deeply at heart and these rumors and suspicious insinuations which are now being indulged in by many editors must certainly be a deep grief to him. In my next I will speak more fully on this subject.

CALIFORNIA TABLE GRAPES.

The following article by Frank T. Swett in For California, gives a view of the California table grape industry and its importance which will give surprise to those not conversant with that phase of California fruit growing:

From time to time for over a hundred years attempts have been made to grow European varieties of grapes east of the Rockies, but without commercial success. There are too many climatic incompatibilities. Cold winters freeze, hot, humid summers breed fungoid diseases of the vine, and copious summer rains split and rot the tender berries.

But in California the fine varieties from Spain, France and Asia Minor find themselves even better off than in their original homes on the shores of the warm Mediterranean. There are dozens of climates west of the Sierras, but the vine adapts itself to all of them. The Sultanina, the beautiful white seedless variety often prosaically called "Thompson Seedless" shows itself a close observer of the thermometer by ripening in June on the banks of the Colorado river. It ripens a hundred days later, in the cool climate of the shores of San Francisco bay, at Martinez, and between whiles in a hundred other localities.

There are perhaps ten thousand acres of California soil devoted to table grape growing. Most of the product is shipped to other States, New York and Chicago being the most notable markets, but so thorough is the distribution that no village in the United States goes without. About two million crates, each holding four square baskets of six pounds each are shipped annually. This foots up a little over a half pound of California grapes for each American stomach.

The Flame Tokay, originally from Spain, is the leading variety. Its large clusters of flame red berries whose thick skins and firm pulp enable it to stand long distance shipments, make it a favorite everywhere. Probably two-thirds of the annual shipments are of this fine variety. Later in the season, when the fall rains have put an end to the Tokay shipments, comes the Red Emperor, with a more rain-resistant skin, and large oval berries of a darker shade of red. While hardly as attractive to the palate, its beauty and remarkable keeping qualities assure its sale at fancy prices. Wealthy New Yorkers, who want a fine table decoration frequently pay a dollar a bunch for the finest clusters. A bright California woman, Mrs. Minna Sherman of Fresno, has put so much originality, skill and conscience into growing and marketing this variety that her brand of Emperors has become famous and remarkably profitable.

From July to December the trains of refrigerator cars are going eastward over the Sierras, grape laden. During that time thousands of men and women find employment in picking and packing. The picking is usually done by men, and though it requires care in the selection of ripe, well-colored clusters and their handling without injury to the bloom, it is the least of the work. Hauled in picking trays to the farmer's packing sheds, the clusters are minutely searched by women and girls armed with scissors, and each bruised, under-sized, unripe, or otherwise defective berry is trimmed out. The bunches are then skillfully laid in the crates, covers nailed on, hauled to the cars, and started on their ten days' journey to eastern markets.

The leading table grape district is about half way between San Francisco and the Sierras, extending through the rich valley soils of Sacramento and San Joaquin counties.

The shipments from California are increasing annually, and new acreages are being planted. With a very moderate increase in the per capita consumption of grapes there would seem to be room for a considerable expansion of the business. A half-pound per capita seems a ridiculously small allowance for any hungry, fruit-loving American citizen.

COST OF BERRY CROP.

Editor Cultivator: It would be quite interesting to learn what expenses were involved in caring for that acre of strawberries Mr. L., of Barbour ranch, writes about in the last Cultivator, and what kind of berries—Brandywine or others.—G. E. Degerholm, Tropico.

* * *

Replying to Tropico letter the expense items are as follows: Beginning with the land after it had been plowed and harrowed and smoothed, ready for marking:

Potting and transplanting	$113.75
Cultivating	56.55
Irrigating	63.85
Picking	350.00
Baskets	150.00
Fertilizer	13.00
Total	$747.15

There are other items that perhaps should be legitimately charged up—as delivery expenses—per cent of crates lost—prorata of management expenses—taxes and wear and tear of tools. At best I should have to approximate them—as also the commission on sales. These latter named items will vary with every grower's situation and as no attempt was made here to segregate the expense items, except as above noted, I shall not offer any estimate.

In my judgment the item for fertilizers should have been not less than $100. Thirteen dollars worth of stable manure was plowed under in April preceding and the land planted to watermelons, which the bugs destroyed utterly, and it was after this that it was determined to set out this same piece to strawberries. I proposed to set potted strawberry plants from pots, in August, believing I could secure a full crop the following spring. I had repeatedly done this same thing on rich market garden land in the East and believed it would work even better here. But the owner of the ranch stood aghast at the idea of buying 26,000 pots at a cost of $5.20 per 1000, merely to try an experiment. As a compromise 6000 were bought and the plants set in rows 20 inches apart and 3 feet apart in the row. This, however, set but little more than half the acre, but as soon as the plants were set out the same pots were used in propagating another lot, which were not ready until the middle of September. In the meantime the first lot had sent out runners which were placed along in the rows and allowed to root—making what is known as the matted row. The second lot, because of late transplanting, threw out no runners. About seven rows of the latter planting were set one foot apart in the row—the balance three feet—same as August planting. As no runners came to fill up the open spaces, these spaces were filled in February from plants grown in the usual way. Our finest berries were from the seven rows set one foot apart in the row. All our rows are twenty inches apart. The variety was the Brandywine—from the very best strain known, and propagated by the greatest care and skill possible. People who are skeptical as to the value of strawberry plants grown properly are cordially invited to visit our grounds. To many the propagating of plants in pots is new, but it is an old process, and the only successful way to set out a large number in hot August or September weather. I have never succeeded with runner plants in those months. Later on, when the plant is not in active growth and the temperature is lower it is easy enough,—Q. A. L., Barbour Ranch, San Gabriel.

RAISIN INDUSTRY.

This industry is an important one in the production of California. The acreage of this product is conservatively fixed at 70,000 acres of producing vineyard, yet, during the past five years, many thousands of acres of raisin grapes have been planted, and it is quite safe that California today has between seventy-five and eighty thousand acres of raisin producing vines.

The importance of the industry is that, as a separate product, more growers are interested, there being about 3500 California growers who produce raisins, and the result causes an active circulation of money that is beneficially appreciated by the grower and merchant.

Raisins produce from $50 to $150 per acre, owing to soil. Aside from one or two localities in the West, California is the only raisin producer of the United States. The system and method of marketing the product compares with the imported raisin in packages and quality, and at least 50 per cent of the California product is being placed on the American market in one pound cartons of seeded raisins—seeded, cleansed and pure of any processing—ready for use in the preparation of puddings, pies, cakes, and for any other use that currants and raisins are required. These goods are sold in the East at 10 to 12½c per pound, and are a household necessity, as there is no labor needed in seeding raisins as in the olden days.

Being a home product the American people should realize that in California, one of their own States, raisins are being produced by a community of farmers who expect and hope that consumers will buy their own home product; superior in quality and modernized by machinery, placing the raisin package in the kichen of American homes ready for use without even washing.

This product of California is commended to the housewife, therefore use it and encourage home production, particularly when you are securing a superior article for the purpose you intend it. If the consumers of our own country can realize that California is producing from 80,000,000 to 120,000,000 pounds of raisins annually for the American market, why not encourage our own advancement and use California raisins.

California raisin production:

1902	100,000,000 pounds.
1903	120,000,000 pounds.
1904	80,000,000 pounds.
1905 (estimated)	90,000,000 pounds.

These results produce 4000 to 6000 ten ton carloads annually.

Drying grapes for raisins forms one of the most prominent features of viticulture as carried on in California. For the last four years average output has been 94,750,000 pounds. Yet, strange, to say, this branch of the industry is carried on in California alone. How very extensively it is carried on here the above figures do not show of themselves. But to produce an average crop of raisins, 330,750,000 pounds of grapes are required. Perhaps California is the only State which can afford to divert such a large part of its grape yield to drying for raisins. It certainly pays, however, for the average value of raisins during the last four years has been $4,374,125.

When the tops of onions become yellow and commence to fall, they are ready to be harvested; they are best dried by placing them in a dry shed in thin layers.

CITRUS FRUITS

By C. A. Day. Pasadena

SCALE AND INSECT PESTS.

Four of the scale which infest the citrus trees of California, the soft brown, soft orange, hemispherical and cottony cushion scale, are kept under control by numerous parasites and at present are not factors in the insect problem. The parasitic insects which attack these species of scale do not in any instance exterminate the scale, but reduce the numbers to the point where it is often hard to find specimens of these scale, but the inspector doing field work will occasionally find all of these varieties of scale in very small numbers or located on a single tree. Perhaps the most effective parasites on any specie of scale is those species of lady birds which attack and effectually control the cottony cushion scale. Four species of the lady bird ordinarily classed by the orchardist as Vedalia, do so effectual work on this specie of scale that specimens of the cottony cushion scale are only occasionally found in our citrus orchards and nurseries. Frequently, however, infections, in a small way are found on nursery stock or from one to half a dozen trees in the orchard show infection. At first the orchardist on discovering such an infection of one or more trees, became alarmed and applied to the State or county commissions for the parasites, but experience has shown that if left alone the scale is soon attacked by the Vedalia and the local colony of scale are completely destroyed so that none are left to be found, but notwithstanding this apparent extermination of the local infection of the cottony cushion scale, the insect is not exterminated and if the parasitic enemies of this scale were removed from our State or through any means should become exterminated, cottony cushion scale would rapidly develop and again threaten the destruction of our citrus orchards.

* * *

BLACK SCALE.

Many of our citrus fruit growers have come to believe that this, the most widespread of our scale insects, is about to be, if not already, removed from the list of injurious insects which require treatment by spraying or fumigation. I personally know of instances where the orchardist has decided not to treat his citrus trees for black scale because of the rapid increase of the scutellista during the last few weeks. And from a reliable source I learn that orders for material to be used for treatment of this scale have been reduced in quantity or cancelled. Will it be necssary this year to spray or fumigate for black scale, is the question that is up to every owner of a citrus orchard. This summer the bulk of the black scale hatched early and in advance time of the ordinary season. The scutellista did not get to work until mid-summer and in many cases, we might say in most of cases, the orchard is well stocked with young black scale and the question asked is shall we spray or fumigate for this scale? My answer to this question, judging from observation and past experience, would be to advise thorough treatment that will destroy all the young scale. The scutellista are now in such numbers that all the old scale which have not hatched out their brood of young have been parasitized and the destruction of all the young scale now out will effectually clean the orchard from black scale and with such treatment the orchard will remain practically clean for the next two years, even though the scutellista should do no better work than in the last two years.

In order to maintain my reputation for consistency I shall have to say that I did not answer the communication of C. F. E. R., of Orange, in the citrus department of the Cultivator of August 4th. I did not, of course, see the specimens of scale sent and the answer may have been in this instance in the main correct. But from my past experience and observation in a great majority of instances the summer and fall hatch of black scale usually, in ordinary seasons, goes over to the next spring and summer before they come into the egg stage. This season there will be no fall hatch of the scale as the parasite will get all of the old scale that would hatch late. On the old bearing orange trees the young scale will mature slowly and the bulk of them will go over until spring before the next brood hatch. And providing they should come into the egg stage in the months of April and May the scutellista, judging from the past experience with this parasite of the black scale, will not be in sufficient numbers to destroy the old scale and prevent the hatching of another brood of young scale next spring and early summer. Another thing, if the rainy season should come early this year, for instance the last of November or first of December, accompanied with cool weather, this will retard the development of the young black scale and check the work of the scutellista.

There is still another point to be considered in the answer to the question whether we shall destroy, by treatment, the present crop of young scale. The young scale hatched out in late spring and early summer will be a heavy draft on the orange tree, now carrying a good crop of fruit and engaged in storing up the reserve material for the blossom and set of the next crop of fruit, the coming spring. In very many instances this present crop of scale, if left without treatment, will materially reduce the set of fruit for the next crop. The present cool summer, with fog from the ocean nearly every night, has been very favorable for the young crop of scale here in the vicinity of Pasadena. There has been no hot days to destroy a part of the newly hatched scale, as occurs in ordinary seasons, and every scale hatched seems to have lived.

* * *

AS TO THE FUTURE.

One thing should be remembered in figuring on the future work of the scutellista. It only atacks the old scale in the egg stage, and the fly propagates rapidly in the hot weather of mid-summer and very much slower in the cooler temperature of late fall, winter and spring. Black scale remains dormant and does not continue to develop when the tree or plant on which it is located is dormant and there is but little flow of the elaborated sap of the tree or plant.

It is a question whether any of the mature scutellista of the summer and early fall live through until the next spring. With a warm, open winter there will be a little work of the fly through the winter and a small stock of parasites will thus be carried through the winter. With a cool, wet winter there would certainly be but a very limited stock of parasites to begin with in the spring. Our experience this year has been a very slow rate of increase of the scutellista during the spring months, the more rapid development of the parasite not taking place until the months of July and August. One discouraging feature which I noticed this year was that the stock of parasites in orchards where they were in good numbers last season, was very small this spring, it being hard in many cases to find specimens of the larvae or pupae under the shell of the scale. A considerable portion of this small stock of old scale on these orchards hatched an early brood of young scale that gives an increased stock of scale to go over to another year.

* * *

INJURY FROM BLACK SCALE

Is in the loss of sap and from the fungus which covers the leaves and fruit. By the loss of sap the vitality of the tree is reduced, often causing a severe dropping of the young fruit, especially when there is a large stock of scale and the orchard has not been fertilized. I have noticed where an orchard has been well fertilized and properly irrigated and cultivated, that it can carry a good stock of scale and set a full crop of fruit. In this case cost of supporting the scale should be considered as included in the sum paid for fertilizer and extra culture. With the black scale removed it will require less fertilizer to obtain desired results. The presence of a large stock of scale will have a tendency to produce small, inferior fruit. Aside from the loss of sap diverted to the support of the scale, the vitality of the tree is further reduced by the heavy coating of smut which covers the leaves, and interferes with the tree's functions of digestion that take place in the leaf. The sunlight shining through the green coloring matter of the leaf separates the oxygen from the carbon dioxide, the former is given off again into the atmosphere and the carbon dioxide is retained as an important element of plant food; the heavy coating of smut on the leaf interferes with this process. The coating of smut which covers the fruit prevents the proper coloring of the fruit and necessitates the washing of the fruit before marketing. The expense of washing, the loss from increased decay due to the additional handling in cleaning, and possible increase of moisture of the packed fruit, added to the inferior quality of fruit and reduced quantity as compared with the expense of treating the scale, is the strongest kind of an argument in favor of cleaning the citrus orchard from black scale.

We shall take up the treatment of black scale in next week's Cultivator, but would say now that the early hatch of scale will demand early treatment or otherwise the scale will get too large for ordinary treatment.

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

CACTI IN SUMMER.

Look after your collection of cacti; it is well to remember that they should be in the full sun even during the hottest part of the year. While this is true, it is equally true that most plants of this nature suffer from lack of water during the summer. To overcome this all pots should be shaded from the sun and the best way to accomplish it is to plunge them in the ground up to the rim of the top—in winter they may be lifted out. Some few cacti do equally well in the shade and these are the Epiphyllums ("Lobster Claws"), the Phyllocacti ("Leaf cactus") and the climbers. All of these latter are liable to injury by frost and should be protected during winter.

* * *

CACTI FOR BEGINNERS.

Echinocereus Berlandieri.—A dwarf growing plant, forming large clusters; extra fine purple flowers which are sweet scented. This is an elegant pot plant. Keep in the sun if blooms are desired. A very showy and satisfactory sort.

* * *

Echinocactus Pectinatus.—This is one of the best blooming cacti that can possibly be obtained. The flowers often measure two to six inches across and are of a bright purplish pink color, and very fragrant. The plant itself is very ornamental, the spines being white and so closely pressed to the stem that they can be handled without harm. There is no other Echinocereus that we can recommend so highly, excepting E. C. Candicans.

* * *

Echinocactus bicolor.—Stems four to eight inches high. Flowers between two and three inches long; petals rose purple; spines all the colors of the rainbow; a very desirable plant and one of the best of the cheap varieties.

* * *

Echinocactus setispinus.—One of the best bloomers to be had, which make up for the little beauty in the plant. Will bloom from early spring until late fall, and then be brightened during winter with coral-red fruit. The flowers are very large, yellow, with a red circle inside and very fragrant.

* * *

Cereus Coccineus.—If flowers are desired this is the plant to get. It is one of the best bloomers, flowering when not more than 4 or 5 inches high. The flowers are of the most intense scarlet, of large size, last for many days, and are produced in abundance. Plants make several stems of one inch in diameter and two to three angularis or Macdonaldi. On these it makes double its normal growth and blooms very freely.

* * *

HOUSE FERNS.

No class of plants grown for their foliage can compare with the exquisite beauty of the ferm for decorative purposes. Their finely cut fronds have a delicacy and gracefulness of habit foreign to other plants. Although they are now quite extensively grown, they are not nearly as frequently seen in the house as their merits deserve. The finer varieties are undoubtedly more difficult to grow than the ordinary run of plants raised for house decoration, but we have many sorts that take kindly to house culture.

Most of the better varieties love heat, shade and moisture in their growing season, and to have nice plants for winter use it will be necessary to grow them in a rather close, cool, shady place during the summer months. For this purpose a frame of sufficient height to admit the plauts

without touching the glass as they grow will answer every purpose to those who have not the convenience of a greenhouse. Those who have plants already and desire to multiply them, may divide them, if that is practicable (some of the kinds cannot be divided) Any good fibrous loam mixed with about one-third of well-rotted manure will supply a congenial material for all our more common ferns.

Young plauts purchased in the spring and repotted into larger pots, will will make handsome window plants by winter. Watering will be about the only care necessary after the weather is warm enough to leave them in the free air constantly. Ferns must never be allowed to suffer from want of water; many of the varieties, if allowed to wilt, will be ruined for the time, and the labor of a season lost. Towards fall more light ought to be given, and a less moist atmosphere maintained in the frame to harden the plants for their ordeal with the dry atmosphere of the living room.

The Immediate Cooling of Fruit

The cyclone system placed in operation by A. R. Sprague in shipping deciduous fruits of the California Fruit Exchange.

Wishing more extended information regarding the cooling system of which many papers have spoken, we have asked Mr. Sprague to furnish to us an account of the performance of his system and description. In the letter accompanying the article, Mr. Sprague says:

The methods are similar to Mr. Powell's methods, excepting they are far more effective, for it was impossible for him to cool a heated car of oranges or fruit short of one and a half or two and a half days, by using special refrigerators and packing in low tiers. During this time, of course, the fruit is degenerating, this process is arrested as soon as it gets sufficiently cool, but it begins again as soon as the fruit is out of the car; while by the Cyclone Cooler process we cool the fruit within a few hours and so quickly as to prevent the beginning of degeneration and hence when the fruit is taken from the car in the East it holds up amazingly well, much better than when shipped greener under ordinary refrigerator methods. I know nothing of the process of extracting the air from the fruit and replacing with nitrogen referred to by Mr. Isaac I understand this is being done in a small way at Antioch and we have made a small shipment in one of our cars for that company.

The description is as follows:

Cyclone Cooler.—The process of cooling a car of fruit by the Cyclone cooler, consists in forcing a large volume of air down through the salt and ice of one tank, then dispersing this blast through the fruit in the car and then sucking it out through the other iced tank and through the condensing chamber, and continuously forcing it through the same path until the fruit is cooled.

Where there are very heavy shipments from one point we use a brine pipe chamber as cooler and condenser, and otherwise use same apparatus for cooling cars except that they are iced after instead of before the application of the cooler. We save twenty degrees of refrigeration by use in the condensing tube of the brine from the salt and ice melting while the cooler is applied.

The time required to make a car of hard-ripe peaches secure from decay during a shipment lasting from one to two weeks varies according to conditions, from one to five hours. When the right temperature is reached the connections with the ice tanks and drip tubes are removed and the car is ready to send on its way with the ordinary refrigeration.

It will be noted that the usual refrigerator cars, of any pattern, are used without modification and the fruit is loaded and braced as now, the cooler being then applied for the time necessary.

In using this quick cooling process it becomes quite immaterial whether the car is delayed a day or two or not, after cooling. It will carry safely. Then too, the fruit may be safely received on the platform, or in the loading shed at any time during the day, regardless of whether or not an iced car is ready to receive it, since the exposure is a slight matter for fruit which is to be thoroughly cooled before shipment.

Twenty cars of all sorts of deciduous fruit have thus far been treated by the Cyclone Cooler, including the most delicate hard-ripe peaches and nectarines, and in no case have these shown any further ripening or degeneration. Fruit soft-ripe and bruised when shipped arrived in the same undesirable condition, but not rotten, as it would have been if not cooled before shipment. If any shipper will get into his fully iced car after it is loaded and then have the doors closed, he will quickly realize what the stifling hot and moist air is likely to do to his fruit. During the two or three days necessary to cool such fruit by slow movement of air from and to the ice tanks such harm is done that the most perfect refrigeration during the rest of the trip cannot prevent its arriving at destination more or less decayed, or if apparently sound it is often so "started" that when brough out of the iced car it quickly breaks down. Fruit quickly cooled before shipment never starts to decay and hence will keep well after leaving the iced car. This was shown in the case of the hard-ripe peaches unloaded from the Oleander car, July 10th in Chicago, and kept in store without refrigeration for a week without decay.

This invention will not make it profitable to be careless in packing or handling fruit, but it will save almost completely from losses in transit the vast tonnage of good, well handled fruit, which now breaks down so badly in transit. In the case of all deciduous fruits, when this process is used, the fruit should be left upon the tree until highly colored and sweet, but still hard. In this way twenty per cent is gained in weight and sweet, high flavored fruit may thus be delivered to eastern consumers.

In the case of citrus fruit and vegetables shipped under ventilation it will doubtless be useful in thoroughly airing out and equalizing the temperature of the fruit or vegetables, and cooling and drying to the desired degree, while for citrus fruit shipped under refrigeration it will prove quite as useful as with the deciduous fruits.

Arrangements are made to promptly supply this apparatus for the use of all shippers desiring it, upon promise of sufficient business at one point to justify establishing such a plant, probably not less than fifty carloads. Payment for the use of the cooler being made by charging a small sum per car. —A. R. Sprague, Sacramento.

General Agricultural Notes

WHEN TO USE LIME.

In the Country Gentleman we note the following summary of conditions under which it is wise to use lime:

1. Where the soil is acid, as in many parts of Rhode Island.

2. Where the soil is a heavy or sticky clay. Lime will lighten up the texture and make it workable. It will lessen the liability of clod formation and make the soil friable.

3. When, as in market gardening, it is desired to sacrifice the organic matter of the soil to quick growth of crops.

4. When clover does not do well. Lime acts upon potash salts to set free a soluble potash compound, and hence it is not true that lime acts alone upon the nitrogen-carrying materials. When clover fails to make a good growth, perhaps making a decent catch, but afterward failing either to make a good stand or to produce a full crop, the farmer should test the matter of the value of lime by applying it to part of a field and noting results. He will probably find that there is a call as well for phosphoric acid and potash, and to part of the area to which lime is applied there should be added these materials.

Do not apply the lime in excess; as a starter, not more than 200 pounds per acre. The English farmer has stopped applying it by the ton, as he used to do.

5. When about to sow alfalfa. Here the demand for some base with which the nitric acid set free by the germ fixing nitrogen in the roots of the legume is imperative, and it is better not to run risks, but to apply the lime before the seed is sown.

* * *

The Ohio Expreiment Station has carried forward a series of experiments testing the value of lime on the rather light soils of the station farm. On a certain series of plats, one end was limed while the other was not. The lime was applied to the corn after plowing and before planting the seed. The rotation was corn, oats, wheat, clover and timothy. The clover failed in 1902 and 1903, and soy beans were substituted. In 1903 the corn was ruined by grubs, and was not taken into account in the tables.

The tables in Bulletin 159 of that station show a notable gain from the application of lime, averaging fully ten bushels per acre of corn, although it was on the clover that the most conspicuous gains were made. For instance, where phosphorus, 20 lb., and potassium, 108 lb., per acre, were added, the gain from lime was 2162 lb. per acre. Here too the gain from the fertilizers was 1124 lb.

Where nitrogen, 38 lb., was applied with phosphorus, 30 lb., and potassium, 108 lb., the nitrogen being in the form of sodium nitrate, the increase due to the lime was 1501 lb. of dry hay per acre. Where the nitrogen was in the form of linseed meal, the gain due to the lime was 1915 lb., and when in the form of either dried blood or sulphate of ammonia, the gain was approximately a ton of dry hay per acre. The influence of lime is here very large indeed, even if the soil be not a clay.

So where barnyard manure was applied at the rate of 16 tons per acre, the gain where lime was also applied was 1503 lb. per acre of hay. Again, where muriate of potash and acid phosphate were applied without lime, they produced no increase in the crop, but where lime also was applied, the gains were equal to those made where large quantities of nitrogen were used. Moreover, the crop was clover, and not largely weeds and timothy, as it was where no lime had been applied. The result is thus stated:

"Reviewing the table as a whole, we see that on the unlimed land the average unfertilized yield of hay had been approximately half a ton per acre, and no fertilizer or combination of fertilizers has materially increased this field, except when used in conjunction with either lime or large applications of nitrogen. Lime alone has nearly doubled the unfertilized yield, and has more than doubled the yield obtained from fertilizers containing no nitrogen, or from other carriers of nitrogen than nitrate of soda or barnyard manure. Nitrate of soda appears to have materially increased the yield in all cases, but it has required the help of some carrier of phosphorus at least, if not also of potassium, to produce the maxumum yield."

Where lime was applied directly to the wheat, sowing on the surface and harrowing in at or about the time of seeding, it did not increase the yield of wheat, but did improve the clover following. This may be accounted for by the fact that the chief use of lime in that particular soil may have been the preperation of the soil for the life of the little bacteria interested in fixing free nitrogen or in converting the humus into forms usable by plants, and therefore lime would have to be in the soil a year or more to accomplish the purpose.

As far as acidity is concerned, the need of lime is shown by the usual tests of the litmus paper, care being taken to get good litmus paper and keeping it away from contact with the fingers. The next test is the failure of the clover crop, failure either to make a "catch" or to grow well and produce abundant crops. The disappearance of clover and the appearance of sorrel is another indication.

After all, the best way to manage in reference to lime is to try it on part of the field, applying varying amounts to adjacent small areas, with and without barnyard manure. Where the lime shows a decided difference in the clover, it is needed, and should be applied in relatively small amounts and often. In a four-year rotation of corn, oats, wheat and clover, apply to the corn, putting it on the surface at planting time.

FRUIT CONDITIONS AT VACAVILLE.

One of the Cultivator's staff writing from Vacaville, under date of August 19th, says:

Several buyers are here who want the fruit, and sales have already been made netting good returns. Today a thirty-ton sale of dry peaches was made to one of three or four bidders. I could not learn the price. The Buck Fruit Co., and the Earl Fruit Co., I believe are the largest firms handling eastern shipments of green fruit. Pears are netting now very good returns, some grapes also going.

Called on Mr. Jas. Smith, who, the past two years, has marketed the first box of cherries in Philadelphia. This year he got $100 and last year $70. Their great pest is what he called a "green measuring worm." Each tree is protected by having a strip of wire screen put around and projecting out and down so the worms cannot crawl up.

The pear blight is very bad here, where it is not being continually cut away. That is apparently the only cure for it yet found.

A MARVELOUS VEGETABLE.

Perhaps no vegetable has excited more comment, been more widely advertised throughout California, or developed more demand, than the Crimson Winter Rhubarb, introduced in 1900 by the Wizard of Santa Rosa. Early recognizing its importance, Mr. J. B. Wagner, of Pasadena, in the fall of 1891, paid the then prevailing fancy prices for the best stock, from which he has developed the finest of plants, and during the past few years built up an enormous business. During the past season many valuable improvements have been made about his home and nursery yards, largely from the sales of this product alone.

A recent visit to the Wagner nursery found the proprietor busily superintending the building a a large addition to his residence, and the response to the query, whence this prosperity, met with a cheerful nod to the rhubarb field.

While at present advertising the rhubarb line, it is really but a side issue to the general nursery and citrus industry which Mr. Wagner has built up within the past few years. Stock true to name, whether the magnificent navel, or walnut tree, the vine or berry, or rhubarb root, such has been his aim. Honest dealing, courteous treatment and satisfied customers have advertised him far and near. His announcement appears upon another page of this paper.

Some have used sawdust as an excellent keeper for sweet potatoes. It should be thoroughly dry; so should the sweet potatoes.

Packers to Be Tried.—At last it seems that the iniquitous combination of meat packers in the United States is to get its deserts. After robbing the people by charging outlandish prices for dressed meats, first having stolen the profit of cattle raising from the producer, and driven into bankruptcy thousands of small stockmen, it proposed to still further add to the crime of its business by advancing the rate on dressed beef. The government then took a hand in the proceedings and ordered an investigation into the methods of the combine. The result was indictment of about a dozen different meat packers. Now it is announced their trials will come off this fall, and the government will use every honorable means to bring the violators of law to terms. The great injustice to the public is seen in the fact that the combine put the price of meat so high the poor could not use it. We have been placed in the position of some of the older countries of the world, where the poor can only buy meat once a month. While wages are higher in this country, of course, our common people have been used to eating all the meat they desired, but the price of a good roast, nowadays, has been equal to half the day's wages of the common laborer, and he simply couldn't afford to buy it. The enormous falling off in the consumption of meat in the United States has been caused by the excessive price charged for it. If the combine can be broken by the conviction and punishment of the packers in the combine, the common people will get their rights.

Of course the contest will be a bitter one. No millionaire packer or meat trust magnate is going to the penitentiary if he can keep from it. The highest priced legal talent will be employed. The labyrinthian mazes of technicality will be thoroughly explored. But the government means business. It will meet talent with talent. Greek will grapple with Greek. No guilty man will be permitted to escape. The facts will be presented. The law will be made plain. The time has about arrived when the merits of an important issue are to be tested. The American people can afford to await with patience for the final result.

* * *

Irrigation and Rainfall.—One of the most successful orchardists in Southern California tells us that he secures excellent results from spraying his orchard once or twice a season with cold water. He has a tank rigged on a wagon, which he fills and going between his trees sprays them, thus removing dirt on the leaves, giving them a chance to breathe freely, as well as washing off any scale. With young trees this has proven a fine tonic. A bath for a plant is just as necessary once in a while as for the human body, and what is good for a plant is equally good for a tree. Care must be exercised to spray judiciously but still there isn't much danger in injuring a young tree if the force of the spray is not too great.

We all notice how trees brighten up after a refreshing rain. This is not entirely due to mostening the soil, but to the cleansing of the leaves and the removal of dust and other substances on them which create an unhealthy condition and retard growth.

Two views exist as to the relative value of irrigation and rainfall. There are those who hold that rain is charged with a higher per cent of the elements which make trees and plants thrive than water which runs through ditches or pipes exposed to the air. Another class holds that water used in irrigation carries with it fertilizing agents, such as mineral from the mountains and from decayed vegetation and is therefore better for plants and trees. Experience has taught some of us that proper washing of young trees gives them life and growth, as also irrigation in ditches by the side of plants, and around trees, keeps them constantly growing. Surface spraying isn't good for plants. Water to be efficacious must run slowly about the tree, much as rain falls, allowing the moisture to descend evenly but not with a force which will bake the ground when it begins to dry out.

Agriculture began in arid regions, and under the practice of irrigation, it is claimed, has been successful in maintaining a denser population in the same area than in regions where irrigation is not practiced and reliance placed on rainfall. Those of us who come from the Middle West know that too much water deteriorates the quality, especially in grain and fruit. It is not in wet seasons that fruit and grain are produced of the best flavor or the largest nutritive qualities. Certain plants require more water than others, but they are not the best for sustaining vegetable life. Where there is excessive moisture the fertility of the soil is sooner exhausted. Wet lands become heavy and obstructive to the growth of many things, for they exclude the atmosphere from the roots, which is an important stimulant to growth. To get the best results the earth must be kept in a loose, well cultivated condition, for thereby the roots take strength and the tree becomes hardy. The same is true of cereals like corn. Philosophy may be resorted to to point out results, but, after all, the homely saying that "the proof of the pudding is in its eating" best demonstrates the facts, and the facts show that irrigation will produce better results, all things considered, than rainfall.

So when the Owens river pours its life-giving current into this, the most wonderfully rich country on the globe, we shall be independent of rains and control the seasons, and the growth of trees, and plants and crops as we choose, making a country possible of supporting a population equal to the cities of New York and Philadelphia combined. Great beyond expression is the future of Southern California.

* * *

Prosperous Farmers.—The Cultivator has been telling its readers, once in a while, of the bright side in the farmers' life, of the things he might do for himself and his family, to lighten the daily burden of a somewhat monotonous existence. For example, once a month take the family and go to some beach resort and spend the day, or go to town and take in the inspiration of the bustling crowd, or get up a neighborhood picnic and hie away to the grove and there rest, exchange thoughts with others and get new ideas on subjects of common interest. It's all a good tonic for man, woman and children. It gives refreshing rest, adds zest to work and brightens the whole scope of the home. These suggestions are again made by the following telegram read in an Iowa paper. It says, under date of August 9th:

"A special Pullman car left Essex for Portland at 7:30 a. m. today. The car will be sidetracked at Denver, Colorado Springs and Salt Lake City. There were twenty-nine persons in the party. They will attend the fair at Portland, and return via a different route."

Think of it! Twenty-nine farmers chartering a Pullman car and "hiking" it off to Portland, to take in the Lewis and Clark exposition and the big towns along the way. Such a thing was not dreamed of ten years ago. Those farmers will go back to their homes filled with new ideas. Their wives will be made younger by the experience, for they will get new and valuable suggestions on domestic economy, as well as how to make their homes attractive. Why, they will get material for thought and gossip which will last them all through the cold winter months—so soon to shut them up within the walls of their Iowa houses.

The farmers of California would do well to pattern after their Iowa brothers. They need not go to Portland, unless they wish to, but they can go to other places and have a good time, for be it remembered that out here in California there are dozens of scenic spots near by, where a day may be spent with pleasure and profit. Take the Cultivator's advice, you toiling farmer, get more enjoyment out of life as you go along. Rest once in a while, work will be better done by recreation taken between the seasons of strenuous toil.

* * *

Let Well Enough Alone.—The reciprocity convention, in session at Chicago last week, developed a new batch of tariff tinkerers under a galvanized name. They call themselves "Dual Tariff Makers," but their ideas are the same, practically, as the tariff revisionists, who have been at work, lo these many years, on one scheme and another, to modify the tariff, with the ultimate end of bringing the country to a free trade basis. It goes without saying, that the Dingley law might be amended in a few particulars, which might be of benefit to the people. No law is perfect and in a country whose powers of expansion are as immense as ours, it is a matter of impossibility to fix a tariff which will be just to each and every interest.

But the question we should ask ourselves when we undertake to remodel the present law is, can we adopt another which will be as satisfactory, all interests considered, as the one now on the statute books of the nation? Experience has taught us that every time we undertake to better the tariff law we incite a period of unrest, financial embarrassment and finally bring about hard times. The only thought Congress should have is, can we better our condition, can we add to our prosperity, can we grow as much, under a reciprocity tariff, so called, as we have done under existing tariff rates.

The experience of business men has been varied. Of course, some years we have not seemed to go ahead as we would desire, but in the long run, in the course of the progress of the nation through the country, we have steadily grown. Our industries have enlarged, our wealth increased, our country matured, our social, educational and spiritual greatness manifested to a remarkable degree. All this is the test of our national tariff law.

The Pacific Coast is, perhaps, in the most critical position to be effected by tariff tinkering of any portion of the country. Its geographical location, ports of entry and developing industries would make it most sensitive to any changes which would disturb the business conditions of the country. As a general rule this fight on the tariff comes from persons who are not students of political economy. They do not understand trade laws, but they seize upon this time-discussed subject to hoist themselves into prominence as political oracles.

The Cultivator, of course, is not, in any sense, a political organ. It does not meddle with the views of statesmen as politicians, but when a question of national economics is brought forward, which, if adopted, would injure the whole country, it has its own convictions of right and wrong and does not hesitate to express them. So of this dual tariff talk, we have only to say, it should be handled afar off; its glittering generalities are too transparent, at present, to permit of finding serious lodgment in the minds of the members of Congress. Let us remember that our tariff policy for the last fiscal year brought the American people over half a billion dollars paid for manufactured goods sold abroad; of this amount California received indirectly a very large per cent of profit. So for the present, let well enough alone, and only disturb our trade relations when necessities of gravest importance demand a change.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Almond picking has commenced in Tehama county.

Early pears are being shipped out of the Pajaro valley.

Corning is shipping a carload of peaches daily to the Sanitary Fruit Co., at Red Bluff.

Prune buyers are reported as offering four cents per pound around Vancouver, Washington.

The Oregon apple crop is reported good this season. Pears are light and prunes only medium.

About 125,000 pounds of fresh peaches are being handled by the dryers and canners at Corning daily.

Three thousand dollars was the price paid last week for the peaches on a ten acre orchard near Lodi.

W. F. Coulter, of Fullerton, will receive over $9000 for his late oranges from eight and one-half acres.

There have been shipped from Riverside to date this season 550 cars of oranges and 483 cars of lemons.

A new citrus packing house will be erected at Globe, Tulare county, this fall for the use of independent growers.

The big packing house of the Simpson-Hack Co., at Watsonville, is to be again enlarged to handle this fall's crop of fruit.

The San Fernando Press states that C. D. Hubbard, of that place, recently shipped two cars of lemons which netted him $2870, f. o. b. Fernando.

Brun & Chaix have erected at Oakville, Napa county, a large grape crusher to facilitate the handling of grapes at their noted winery.

The California Winery at Sacramento will soon establish a branch institution for the purpose of crushing and distilling grapes at Woodland.

The Citrus Union has shipped from Fullerton the past season 218 cars of oranges. The price received is said to average from 30 to 40 per cent more than last year.

Apple growers of North Yakima, Washington, are beginning to make changes in their orchards by top working the trees to Esopus, Newton and Jonathans.

A correspondent writing from Santa Clara county says that prune drying is on full blast. Most of the apricots are gathered, also early peaches. Canneries are all running up to full capacity.

It is announced that G. Harold Powell will be returned from Washington to Southern California to make permanent headquarters. Mr. Powell will lead in the fruit shipping experiments.

L. J. Bennett at Marysville has a Bellflieur apple tree that has a big crop of excellent apples now ripening. In the same branches are loads of blossoms that have been blooming for the past week.

The Horticultural Commission of San Bernardino county is warning all ranchers who have Russian thistle growing on their lands to clean out the pest or have the cost of doing the work charged up to them by the county.

On Monday of last week a car consisting almost entirely of Malaga grapes, from Fesno, was sold in Chicago for $2741. This is the highest price ever paid for a car of this fruit in the East.

The high price received two weeks ago for California fruit in the East was kept up last week, growers receiving from $1534 to $2741 per car for fruit. This not only for two cars but for dozens of cars.

Sheriff Bros., of Healdsburg, last week purchased sixty tons of fine prunes at Geyserville, for which they paid five cents a pound straight for most of them. This is the highest price paid so far this season.

The Rialto Citrus Union has purchased the packing house occupied by the O. & L. Association and announces that it will continue to sell its crops to the buyer offering the best prices, independent of any agency.

The Healdsburg Enterprise says that prune growers in the vicinity of Geyserville have been offered four and a half cents straight for the crop this year and many are refusing that figure, holding for a higher price.

The orange growers in the San Dimas and La Verne district had a general meeting at their packing house Tuesday. After luncheon, addresses were made by several Eastern agents of the California Fruit Exchange.

The Indian Hill Citrus Union of Pomona, will pay its members $.85 for packed boxes of fruit of all kinds shipped since last November. This will be four cents more than received last year. The increase in price means about $2500 to the growers.

The grape season starts off very promising. The Malagas that have been shipped have brought fine prices. Only a few Tokays have been shipped and they have been well received. This latter crop promises fine, and growers undoubtedly will receive good prices.

The latest report on the grape crop around Lodi is to the effect that wine grapes will yield about one-half a crop, excepting the white wine variety, which will go about seventy-five per cent. The Tokay crop, while hurt some by the hot weather, will be a very fair crop.

J. A. Montgomery, of Rivera, secretary of the Walnut Growers' Association, in a recent interview, stated that the crop around Rivera would probably be heavier than last year, but that the outlook for walnuts in the whole district was not as good as at this time last year.

The horticultural writer in the Ranch, published at Seattle, last week, says that within two days apple buyers from Australia and other places, called on him to find where they could secure the best apples grown in the north coast States. These inquiries indicate that apples will be in demand this fall.

Last week practically closed the shipments of Bartlett pears from the Suisun valley for the season. About two hundred and fifty carloads were shipped from Suisun, which was about one hundred cars short of last year. Notwithstanding the short crop, growers received satisfactory returns for the season, on account of high prices.

The Whittier Citrus Association held their annual picnic at their packing house Tuesday, August 21st, the ladies preparing a sumptuous dinner for the occasion. Short addresses were made by President Story and General Manager Woodford of the Southern California Exchange, and Secretary Reid of the Semi-Tropic. Short talks were also made by several local speakers and with the very pleasant musical and refreshment features the members of the association spent a very pleasant and profitable day. This is one of the strongest and best associations of Southern California, and Whittier has received an impetus in growth from the fact of its strong financial backing of the surrounding country. The walnut, lemon and orange industries have proven very profitable in this section the past season.

AGRICULTURE.

The Chino sugar factory commenced its fall campaign Monday of this week.

The Lima bean crop of several thousand acres in the western portion of Los Angeles county promises a big yield.

The Oxnard Courier says that the Lima bean crop this year promises to be the biggest in the history of Ventura county.

The Brawley News says that about twenty-five acres of Bermuda onions will be planted in the vicinity of that town this fall.

It is rumored that H. W. Hellman, of Los Angeles, has bought the Dixie Thompson bean ranch in Ventura county, for H. E. Huntington.

A. C. Pickett, appointed by the State University, is at work in Southern California testing fertilizers, under the State law recently enacted.

The La Habra Vegetable Growers' Association at a meeting last week decided to incorporate and have a salesman at the old Los Angeles market to handle their products.

A dispatch from Ventura county states that black-eye beans have again risen in price and are now selling for $3.50 per hundred, and dried apricots are over the seven cents a pound mark.

The big sugar factory at Spreckels, near Salinas, will commence its fall compaign about September 15th. The supply of beets immediately around the factory will be larger than for a number of years.

It has been decided that the big Jones ranch of 12,000 acres, in Sonoma county, will be all put under cultivation. About one thousand acres will be plowed up this year and the balance as soon as possible.

Shipments of beets from around Smeltzer and Benedict, Orange county, commenced last week to the Chino sugar factory. About two hundred and fifty cars will be the size of the crop this year from that locality.

Hop picking will soon commence at the Horts Co. hop ranch near Tehama. The ranch now has one hundred and twenty acres first crop vines which next year will be increased to five hundred acres, chiefly because of the good showing made.

A display of particular interest to agriculturists is to be made at the State fair by Mr. F. M. McMillan, of Fair Oaks, Sacramento county. He will show forty varieties of wheat grown on his experimental farm, his labors having been prosecuted principally with the idea of increasing the percentage of gluten in California-grown wheat, and he has co-operated with Professor L. A. Fritz, of the Federal Experimental Station, near Chico.

LIVE STOCK.

About forty head of horses, all blooded stock, will be sold at public auction at Santa Paula September 9th.

Thos. Green of Spadra recently shipped a car of hogs to Los Angeles, receiving for the lot within a few dollars of $1100.

Two hundred head of sheep were shot in Wheeler county, eastern Oregon, this week, which promises to open up the old range war.

Fred B. Smith, of Los Angeles, has made a proposition to dairymen at Brawley, in the Imperial country, to build a $20,000 creamery and ice plant.

MISCELLANEOUS.

Railroad officials say that a larger number of home seekers will come to California during the coming season than ever before in its history.

The new pumping plant installed by the Anaheim Water Co. is now lifting two hundred and seventy-five inches of water, which is being turned into the Anaheim ditch.

A dispatch from Elsinore states that Messrs. Holdman and Houk, bee men, are loading a car of honey for shipment, price on same being over nine cents. Eastern buyers are also reported in the market looking for comb honey.

Wm. Lehr, of Forestville, Sonoma county, will add about ninety thousand gallons to his cooperage, also a modern still and large hydraulic wine press. He is also building an annex to his winery with a floor space of thirty-seven by one hundred and thirty feet.

According to returns from Utah State Board of Equalization, based on 1905 assessment, that State has $2,139,000 worth of horses and mules. It has 217,600 head of cattle, valued at $3,510,000, an increase of 13,000 head over last year. Sheep also show an increase of over 40,000 head and are valued this year at $3,922,000.

The annual convention of the National Irrigation Association, which opened at Portland on Monday, is a big success, over one thousand persons being present when the president called the first session to order. Men prominent in irrigation affairs were present from all over the United States and many strong papers were delivered.

Among the lines of work offered at the Polytechnic school at San Luis Obispo for the coming year are Physics and Electricity. Students in the course in Mechanics will have most to do with these branches, being engaged with one or both of them during the three years of the course. Students in Agriculture will have class room and laboratory physics during their third year, and will devote sufficient time to gain a comprehensive grasp of its most important features.

C. H. SESSIONS, ASSOCIATE EDITOR

AMERICAN BACON HOGS.

Our bacon hog differs considerably from the English bacon hog. There is, however, a growing tendency toward the typical bacon hog. The indications point to the fact that we are at the "parting of the way," and that in the future we will have a place for the ideal bacon as well as the fat or lard hog.

Corn is at present being used for other purposes, such as the manufacture of corn starch, whisky and oil, The latter is used for various purposes, as for lubricating, a table oil, as a substitute for olive oil, linseed oil, etc. This has caused the price of corn to go up to nearly what other grains, used as hog feeds, are worth. At the same time a ration of all corn, which usually forms the principal part of the feed of the fat or lard hog, is coming to be generally recognized as detrimental to the best development of swine from the breeder's standpoint. These things are the cause of a gradual drifting toward a more mixed ration in swine feeding, and usually a ration containing more protein or flesh forming material. Coupled with this, there is not so great a demand for fat pork as there formerly was, and shipping and cold storage facilities are much better, consequently more fresh and lean meats are used.

These various factors are gradually, but most surely effecting a change in the character of swine in the United States. The all fat hog of the past will in the future be partly replaced by the bacon hog, and the fat or lard hog as a whole will in the future more nearly approach the bacon hog in form than in the past. Of course, there will always be a demand for lard, consequently there will always be a place for the fat or lard hog. But the bacon will occupy a more prominent position in the future than he has in the past.

There is a demand from foreign countries and more largely from our own country, for bacon, and there being few bacon hogs to supply the demand, the trade is supplied from the lighter hogs of the fat or lard hog type. This bacon, however, does not command so high a price on the market as does bacon from typical bacon hogs. The bacon hogs under consideration here weigh from 155 to 195 pounds, and range in age from six to eight months. They are simply hogs selected from the light hogs in general, that conform as nearly as possible to the bacon type. They are not very fat, have fairly good development of muscle, or lean meat, and are as long and deep inside as is possible to obtain them. About 20 per cent of the light hogs that come to the Chicago market are of this type.

Choice bacon hogs are the best of this class; they are hogs that show good lenghth and depth, good quality, and are smooth, well developed and not very fat. They are hogs that have had considerable exercise and have not been fed on an exclusive corn ration. These bacon hogs are selected for the most part from shipments that come from outside of the corn belt, where the principal feed is similar to that used in Great Britain, Denmark and Canada for bacon production, viz., oats, barley, rye, peas, skim milk and pasture.

These are the feeds that are conducive to the production of the best bacon when fed to hogs of the bacon type, and when fed to hogs of the fat, or lard hog type bacon hogs such as we have under discussion here are produced. These bacon hogs have more fat on the outside and less lean meat on the inside of their carcasses than the typical bacon hogs, but are better in these respects than the typical fat or lard hog. In truth, this bacon hog is an intermediary between the fat or lard hog and the typical bacon hog, being more like the former than the latter.

The good bacon hogs of this class may be of poorer quality, may be lower in condition or may be too fat or too much of the fat hog type. Any one or all of these conditions would be the cause of hogs grading lower than choice.

If there is still more marked deficiency in these characteristics, the hog will grade as a common bacon hog. But this hog has sufficient quality and condition to show that he has been well fed and has been fed so that his sides will do to cure for the cheaper grades of bacon.—William Deitrich in F. S. J.

THE GOOD DAIRY COW.

The pail is indeed the only true criterion of the large milker and of the big butter producer, says Dairy Produce. One of the most instructive exhibits in my collection of dairy facts is a number of life portraits of great milkers and butter cows; but it would puzzle any good judge of such cows to select the champion cow out of the lot of over fifty portraits.

A heifer coming fresh in June would have the best opportunity of making a good udder, and of course, the better the form or yielding ability of the udder, the more the cow would be likely to develop into a good milker. The first year of a cow's life will almost surely make or mar the future of the animal. But is is not sufficient alone, for a cow is growing in form and ability to milk for at least four years. I have known cows neglected for even three years after that age to make most excellent milkers, improving as buttermakers yearly up to five years or even more.

Great importance is justly given to inheritance. But heredity only gives the ability to develop parental qualities; it does not give ability to make something out of nothing. Thus selection of parents is only the first element in the culture of good qualities in animals. It is the sowing of the seed; but good seed must be sown on good soil to insure a satisfactory product. Inheritance does not give good qualities any further than to enable the offspring of good parents to develop by the aid of their natural inherited abilities the good character of the parents. The inheritance is only developed by proper training; and it is the best culture of natural abilities which develops the possibilities of them. This training must start from the day of the heifer's birth, and continue, without failure, until the cow, so reared develops into the maturity of her powers.

There are instances in which this natural ability may have been made dormant by neglect, and for years the cow has shown no special excellence either as a milker or a butter producer, until accident has brought out the dormant natural ability. It is also true that good milkers can be made as well as being born. It is well known that calves may be brought to milk when a few months old by the mere massage of the udder which stimulates its growth and premature development. Then it may be reasonably hoped that the calf of a superior milker may be made to succeed the dam in this way by the stimulation of the natural function by the well known process of massage. I have proved the great value of this treatment in the training of calves, and at the same time of the value of training in the way of culture of the appetite, and in the ability to digest ample rations of rich foods.

HOW TO GET BETTER PRICES FOR MILK.

A writer in the Jersey Bulletin gives some ideas on "better prices" for milk which are so pertinent that we repeat nearly in full:

"Want better prices" is the slogan of the dairyman this summer. Prices in the milk markets are governed by the law of supply and demand, of course, but to get better prices for milk than the market prices we shall have to get it cleaner from the cow and take proper care of it until it reaches the consumers. This will require vigilance as well as care, but good clean milk soon earns for itself a demand and a reputation can be built up in a short time.

884 James Flood Bldg., San Francisco

nies of molds on the walls and gives a wholesome effect and appearance. It should be renewed at least twice a year. Whitewashing the walls twice a year may appear too often to some people, but we will lay that down as necessary from a bacteriological point of view. In some countries it is done four times a year, and it is not without good reason; however, time is more precious here and labor higher, so we will try it twice a year until there is trouble from that source. Some folks think if they get it done once a year they are doing well, but that is not sufficient.

* * *

DRAINAGE.

And the barnyard should be considered. The stable and barnyards should be properly drained, and no musty feed or rotten ensilage allowed to lie around the stable; because milk is not so often spoiled by the bad odors which cows may transfer to it through their food, as by the dust that arises from musty feed and the bad smell from ensilage getting into the milk after it is drawn.

* * *

CLEANING THE STABLES.

Clean out the stables at least twice daily; drain off all water if any; sprinkle the floor with plaster every other day. In the absence of land plaster, use shavings from the planing mill, or some kindred absorbent. We will try and do with as little bedding as is consistent to the cows' comfort and necessity and not have too much; otherwise there will be too much dust to contend with, and although it may not be visible to the eye it is there all the same.

* * *

VENTILATION.

Is something that should come next. Each stable should be ventilated with regard to its requirements, and therefore no rule can be laid down as general to apply in all cases. In some hot climates the walls of the stables are one-inch lumber, put up unseasoned, and in summer time there are spaces between the boards of about two inches, yet some owners consider they must have regular ventilating shafts running up the walls!

GOOD MILKING NECESSARY.

To milk the cow right is one of the most important things about the dairy. Careless or inferior milkers must not be tolerated. A slow milker will injure your profits by not doing an important work right. He should be in sympathy with his work. If he hustles through the work the chances are he will not milk out clean and the cows will go dry long before their time.

At the Wisconsin Station the average daily production of milk for one month from 24 cows was increased 4.5 per cent by means of better methods of milking and fat 9.2 per cent. The average gain in milk per head per day was one pound, .09 of a pound. —Successful Farming.

ANOTHER GOOD JERSEY.

From Official Tester Burgess, of the A. J. C. C., we have the following:

Seven day authenticated butter fat estimate of Miss Hazelton 2nd 148309, H. N. Williams, owner, Compton, Cal.

Date.	Milk, lbs. oz.	Test, per cent.	Fat, lbs.
Aug. 9, a.m.	22.	6.2	1.364
Aug. 9, p. m.	17.8	3.8	.490
Aug. 10, a.m.	21.0	4.0	.840
Aug. 10, p.m.	22.11	5.8	1.315
Aug. 11, a.m.	19.4	4.2	.808
Aug. 11, p.m.	19.8	3.9	.760
Aug. 12, a.m.	21.10	5.3	1.156
Aug. 12, p.m.	19.18	6.3	1.228

Aug. 14, a.m.	21.12	4.6	1.000
Aug. 14, p.m.	20.6	4.1	.837
Aug. 15, a.m.	20.10	4.0	.825
Aug. 15, p.m.	20.10	3.8	.783
Total	289.9		13,473

Butter 85 per cent fat, 15.85 lbs. Average per cent in milk, 4.65; actual weight of cow, 945 lbs.

Her greatest production of fat was on August 12, when she gave 41 lbs., 2 oz. milk that indicated 2.384 lbs. of butter fat, equivalent to 2.80 lbs butter, 85 per cent fat. Her great yield of milk was on August 13, 43 lbs., 2 oz.

The reason her test varied rather more than usual was that she came in heat August 11th. The average per cent of fat in milk will show the richness of the cow at normal when in full flow of milk.—C. S. Burgess, tester A. J. C. C.

STUDY COUNTS.

It is as clear as noonday that the amount of profit a farmer gets from his cows can be measured by the amount of intelligence he puts into his work. The amount of intelligence is accurately guaged by the amount of dairy reading he peruses.

Intelligence is on top everywhere. Ignorance of dairy work, of right methods, is found in great abundance among farmers who have kept cows and barely squeezed through all their lives. Indeed, we find that the young man who is just going into the business is a great deal more apt to try and inform himself than the older farmer who "knows all about it."—Hoard's.

POWER ON THE FARM.

Along with improved machinery for farm use has come a necessity for cheap farm power. Gasoline engines will undoubtedly become the universal power used on most farms because they are easy to start and no time is lost in firing for steam. A gasoline engine can be started at any time, night or day, in less than a minute's time and give full power, and then can be left for hours at a time without attention, if necessary, and there is no danger of an explosion. A coming novelty in transportation is the gasoline car, by which a car is operated on railroad lines with greater speed than the steam car or trolley, and at a less expense.

The manufacturers of these engines have simplified these machines so there is nothing about them but what can be understood by a little study by one of ordinary intelligence. The cost should not keep the farmer from purchasing because machines are manufactured small enough for the average farmer's work and powerful enough for the large farmer to use to an advantage. The first cost is the only real item of expense. It is an ideal power for the farm and there are so many places in which it can be made useful. There is the feed to grind, the wood to saw, the separator to run, the shredder, pump, cornsheller and hay cutter to drive, and by mounting the machine on trucks, much work can be done for neighbors who are willing to pay for work that they could do were they but wise enough to purchase a machine.

With the scarcity of labor, the farmer must look for devices in machinery that will do efficient work and save labor expenses, a machine that can be depended upon to supply power at all times at short notice. The small gasoline engine on the average farm is fast meeting this want.

Do every possible thing to prevent dust in the cow stable. Sprinkle land plaster over the floor after cleaning. It will absorb all liquid and preserve boards. Do not allow cows to dry up during the later part of summer as this necessitates keeping them through winter giving a smaller flow of milk than they should.

A good and durable whitewash is made as follows: Slake a half bushel of fresh lime with boiling water; dissolve six pounds of fine salt in water and thoroughly mix this with the slaked lime, thin with hot water and apply it while quite hot.

LARGE OR SMALL COWS.

It is hard to make the average farmer think that size in dairy cattle is not a criterion of ability and profit. In a great many matters we judge by what we like and not by what we know. Prof. T. L. Haecker, of the Minnesota dairy school, takes up this question in a very practical way by comparing two cows as they stood at the experiment station. He says:

"The large cow is the deepest milker in the herd, while the small cow never gives a large mess even when fresh. The large cow invariably decreases rapidly in her flow, while the small one is a persistent milker, generally giving as much in the spring as when she went into winter quarters. The large cow, during the past three years has averaged 295 pounds of butter per year, while the small one gave 341 pounds. The large one yields 3 per cent milk, while the small one gives 5.5 per cent milk."

Now, in the above case Prof. Haecker judges by what he knows. He takes actual facts as a basis for his judgment. But how is a farmer going to take facts as a guide when he never made a test of his cows or kept any sort of record and has no basis of judging a cow except in a loose general way. He has always liked large, meaty cows and there is the end of it with him.

Many a time have we seen herds of big cows that were not returning enough money to more than barely pay for their keeping, but the owners liked just that kind of cows, and that was all there was to it. Any attempt to get them to look deeper and accept a different basis for their judgment and management was resented in most cases.

With a great host of dairy farmers, all progress toward better understanding of the true principles that govern in their business is like pulling a cat by her tail to her dish of milk. She will do what she can to prevent progress. And even though she eat the milk after she gets to the dish, she never thinks well of the man who got her there.

It takes a long time and much thinking and practice to get so we are governed by our reason, and not by our likes and dislikes and the cow question is no exception.

DAIRYING IN CALIFORNIA.

Northern California farmers ought to read the article on Dairying in California contributed by Charles D. Pierce to the current issue of the Live Stock and Dairy Journal. Mr. Pierce is president of the Pierce Land and Stock Company, and his object is to promote an extension of the dairy industry throughout the State.

Mr. Pierce is well qualified to write on such a subject. His own herd of cattle has been singularly successful and is proof of what can be done along this line in Northern California when enterprise is combined with intelligence and a thorough understanding of the subject. Mr. Pierce now has 400 head of Holsteins, in his opinion the best possible breed for dairy purposes. Sixty of his cows have produced an average of over twenty pounds of butter each in a seven-day official test. During the course of one month the milking herd of 145 cows produced 150,000 pounds of milk, or an average of 1035 pounds each. With such a record as this Mr. Pierce needs no excuse for his enthusiasm nor for the energy with which he would persuade California farmers to imitate his profitable example.

Dairying is a great industrial possibility for the State, and it ought not to be neglected merely because other industries have a priority in point of time. Every factor that can conduce to success is present in California. The climate is ideal for the purpose, inasmuch as stock can be turned out all the year round, while the soil produces luxurious grasses and feeds of many kinds. Mr. Pierce's prediction is therefore a safe one, that California will become one of the great dairying States of the Union. There is, indeed, no hindrance to this consummation except an unwillingness on the part of farmers to change their manner of working and to adapt themselves to new opportunities.—Sacramento Union.

The heifer is quite apt to form her milk habits after birth of her first calf. If at the end of the second year's milking, the heifer is failing to do profitable work, she should be discarded.

Get acquainted with your cows. By this we mean find out how much they give, how much butter or cheese they make and how many of them in the herd are paying for their board.

With milk as a starter, pigs soon learn to eat slops made of mill feed.

A little oil of pennyroyal or oil of cloves will drive fleas away from the stable.

SUGAR-BEET-PULP
A Cooked "Cow-Breakfast-Food"
TO FARMERS, STOCKMEN, DAIRYMEN:
SUGAR-BEET-PULP, 60c per ton f. o. b. cars or wagon, fresh from factory. Professor Carlyle has demonstrated that 3¾ pounds of sugar-beet-pulp equal 1 pound of alfalfa hay in feeding value; and that 3 pounds of hay equal 1 pound of corn in feeding value. Hundreds of satisfied users have proved it to be the cheapest and best dairy food in California. Write for freight rate if too far to haul.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

THE DRY FOOD HOPPER.

Everything that has life in it has to have food of some kind. No one will deny this assertion, and I think it may prove helpful as well as interesting to our readers to take under consideration some of the different feeds and different ways of feeding poultry.

You all know by this time the three conditions of egg production: Comfort, exercise and proper food. Today we will examine one of the different methods of administering the proper food.

Dry feeding, or wet, which? Now as a preliminary let me urge upon our readers not to make any change in their way of feeding, if they are successful not only in raising thrifty chicks to maturity, but also in having a healthful flock of good paying, laying hens. Changes, sudden changes, in the food are disastrous to the egg basket, so make changes gradually and cautiously.

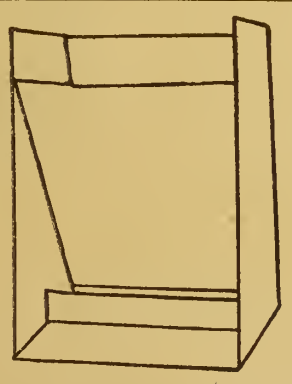
Some years ago there appeared for a year or more an advertisement in some of the California poultry journals of the Sampson method of feeding, which Mr. Sampson offered for sale at $1.00 for the prescription, promising that it would be a preventive of roup or any illness and would induce hens to lay all winter. A dollar was a dollar in those days to me, and just as I was wondering if his prescription really amounted to anything, I received a letter from a friend telling me she had been recommended to feed her hens a dry mixture, which she said was a secret, and she wanted to know what I though of it. I asked in reply if it was the Sampson method and she said it was, and she thought it pretty good. The plan was to feed this in the morning, giving the hens in their troughs what they would eat up during the day.

I decided to try it myself on some of my pens, because daughter and I found the carrying and lifting of the heavy buckets of mash for some hundreds of hens quite arduous work.

The mixture (not mash, for there was no water in it) that I fed was the ingredients of my mash—two parts bran, one part rolled breakfast oats, one part feed meal (corn meal) and half a part of meat meal (the meat meal was omitted on the days when I fed green ground bone). I put this into the troughs of a morning and the hens rushed for it, but as it was dry they could only eat about three mouthfuls without water, so they ate a little food and then took a drink. They did not seem to like this plan at first and soon jumped into the scratching pen to hunt for stray grains, but whenever hunger pressed they would return to the dry trough. They drank a great deal more water than formerly. The worst of this way of feeding was that the fowls scattered a good deal of the dry stuff hunting for something better at the bottom or picking out the oats. I had not then thought of making hoppers for the dry feed. I found this method greatly lessened the labor and the hens did well. In fact the only thing unsatisfactory was that I could not utilize table scraps, small potatoes, and a ton of beans which I had bought very cheap. Cooked vegetables and such things went into the mash, but could not be put into the dry mixture. One thing greatly in favor of the dry mixture was that the fowls did not, or could not over eat, and yet had plenty, they never went hungry, never ate too quickly, never had indigestion and were vigorous and healthy.

Some little time after this experiment of mine, which lasted over a year, I heard of Dr. Nottage and his plan. He was called "the man who feeds his hens twice a week." Later I read of Mr. Parks, whose Rhode Island Reds are famous, and who tells how successful he is in a most interesting article on this subject, and last, but not least, I read Dr. Sanborn's description of his method of hopper feeding and its results. It is always interesting, and frequently very helpful to hear of the achievements of others, especially when it depicts the actual doing of things by one who has made a success of the undertaking. I intend therefore, giving a synopsis and extracts from the articles of these three noted experts on the subject of dry feeding. Of course these articles are too lengthy to be given in one week's Cultivator; they will be continued for at least two weeks.

Meanwhile I give a rough plan of a dry hopper, which I myself have just made, for I am using the dry hopper feeding plan for my thirty-eight young



stock. I have not lost one chick from the time they were hatched. I fed them the dry chick feed from the first, following this with dry wheat, kaffir corn and rolled oats, feeding in addition all the green vegetables or lawn clippings I could get and failing that, the alfalfa meal.

Now I am feeding, in either the hopper or a deep old soup kettle I have, the following mixture dry: Two measures bran, two measures alfalfa meal, one measure corn meal, half a measure beef scraps, half a measure rolled oats. This I fill every morning. I give them lettuce, melon rinds, scraps of vegetables, and at night a feed of Kaffir corn and wheat, fill their drinking vessel twice or three times a day. I have not had one sick or dumpy or ailing in any way since they were hatched. I find the way to prevent their wasting or scattering the dry feed is to have it in as deep a receptacle as possible, so I have made the feed

Must Hatch Incubators and Brooders HAVE STOOD THE TEST
Manufactured at Petaluma, the Chicken Center of the World. Beware of Others "Just as Good."
We hatch and prepare little chicks for shipment to all points within sixty hours' travel of Petaluma. July, August and September the best months to hatch chicks—they will commence to lay in the winter months. Place your orders at once for this season's hatch. We also supply White Leghorn eggs for hatching. Prices on application. WRITE FOR CATALOGUE B.
MUST HATCH INCUBATOR CO. - PETALUMA, CAL.

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

trough of the hopper three inches deep, the kettle is twelve inches deep, and I fill up to three inches from the top. A tin bucket can be nailed against the house so that it cannot be upset, or a hopper can be made out of a five gallon oil can, and either wired or nailed against a post to keep the fowls from tipping it over.

The hopper I made from a Bishop's cracker box in about half an hour.

(Continued in our next.)

* * *

EDITOR'S QUESTION BOX.

Sick Turkeys.—(Mrs. W. B. R.) Among my bunch of about one hundred turks I have some 15 toms (young ones) weighing in the neighborhood of 12 to 15 pounds, which are beginning to be affected with a sore head. The red part of the head swells up and scabs over. Inside of the mouth is all swelled up and whitish color. An early answer telling what ails them and what to do for it will be very gratefully received.

Answer.—Your turkeys have roup and possibly canker. The best plan now is to rub their heads with carbolic salve or carbolated vaseline, and paint the white spots in the mouth, if they are canker, with a solution of sulphocarbolate of zinc, two grains to the ounce of water. If it is roup add two grains of carbolic acid and two grains of alum and twice a day swab or paint the mouth. Give at the same time a pill of quinine every other day, and if in two days they are not well spray the mouth and throat out with peroxide of hydrogen. Keep the sick away from the others, as it is very infectious.

* * *

How to Begin.—(Mrs. J. L.) Since we take the Cultivator I have been very much interested in your articles about poultry and should like to ask your advice about several things. We are trying to make a start in the poultry business, but do not know which is the best way. What do you think best: hatch your own chicks, buy them, or buy young pullets or two-year old hens? Do you think we can hatch now or is it better to wait till spring? We have about 100 pullets three months old. I am feeding them in the morning a mash consisting of equal parts ground barley, corn meal and bran, and for every ten parts of these ingredients one part of meat scraps and bone meal. At night I give them grain (wheat and cracked corn). Do you think I feed too much corn? Some people tell us it is too heating. Then, how much is a good ration for 100 pullets? Sometimes I think I feed them too much.

Answer.—If you had mentioned what breed you intend keeping I could answer your letter more satisfactorily, as some breeds mature more quickly than others and require different handling. As to which is the best way to commence, it very much depends upon your pocketbook, also on what lines you intend breeding, whether for only eggs for market, or for fowls for market, or fancy stock for exhibition. If you want eggs for market this fall and winter, buy pullets hatched in March or April. Set aside in one pen by themselves eight or ten of the best of these with a good vigorous male and keep their March and April eggs for hatching. Or buy eight or ten young hens a year old that are through their moult and keep those for your breeding stock, commencing to hatch in October and hatching every month till May.

You can make good money by buying pullets now, but be sure you get them from healthy stock, and that they are healthy themselves, and if you are a novice in the business go slowly. You can learn the business much better and with less cost to yourself with a few fowls, and then, if you succeed, gradually increase your flock.

I think you are feeding too much corn meal, in addition to the evening meal of corn and wheat. Even for Leghorns you had better feed two parts of bran and one part each of corn meal and ground barley with one tenth meat scraps and bone meal, and be sure to give plenty of green feed. Give the young pullets all they will eat. You cannot feed young Leghorns too much, and as you write from Petaluma I suppose you have Leghorns.

* * *

Australian Salt Bush, Etc.—A Subscriber): Could you kindly inform me through the poultry department of the Cultivator where I can get Black Orpingtons? Do not refer me to the Orpington ranch at Los Angeles. 2nd. What is the best method of obtaining charcoal for chickens? 3rd. Would an Australian salt bush patch make good runs for chickens in pen? And would it stay green through the summer without irrigation and take the place of alfalfa?

Answer.—I do not remember the name at present of a Black Orpington breeder.

2. I buy common willow charcoal at the feed yard, pound it up and then grind it in my gristmill. You can purchase it at any supply house already granulated.

3. Yes. Australian salt bush makes a good run for chickens after it is once started. It remains green for a long time; it has small seeds at the branching of the leaves; the hens like the salty taste of these seeds and of the leaves, but it does not quite take the place of alfalfa.

* * *

Turkeys.—(W. F. K.) I wish to know if young turkeys are being hurt by eating prunes, and what effect would peaches have on them if they eat all they want?

Answer.—Prunes do not seem to hurt young turkeys as much as peaches. Peaches for quite young turkeys, if eaten too liberally will clog the stomach and give indigestion and diarrhoea. These fruits do not hurt the old turkeys.

* * *

Turkeys.—(H. W. R.): I wrote you some days since about some of my turkeys having sore heads, and now I have more trouble. Some of my half grown turkeys have what seems to be enlarged crops. There is a large bunch hanging down from where the crop is located, about the size of or larger

than a large orange, and hangs so low the turks feet strike it when walking. When I hold turks up by heels water and grain the turk has eaten runs out of mouth and bunch gets smaller. Can feel grain in bunch. Kindly tell me what ails them and what to do.

Answer.—There is something wrong in your management or feeding of the turkeys. The symptoms denote a lack of grit. Your turkeys are suffering from indigestion and sour or impacted crop. Give charcoal and grit to all. And for those affected give a tablespoon of castor oil and knead the crop gently. Feed soft food, bread and milk, with a little cayenne pepper, and when they get better give a pill of quinine and turn them out on free range.

* * *

Spinal Meningitis.—(A subscriber.) Will some reader of the Cultivator tell me the cause and remedy for this disease in my chickens? About two months ago I noticed one of my Black Minorcas acted as if she has a crooked neck. We caught her and examined her for some cause, but could find none, but she steadily grew worse, that is, she drew her head more to one side, would eat and seemed well in that respect, but got so bad that at last it drew her head so that she could not stand and finally would lie on the back of her head, and when we saw her grow worse we killed her. I have another beginning the same way. Her head is drawing to one side and yet she seems perfectly well, scratches and eats as heartily as any of my flock.

Answer.—Your Minorca has spinal meningitis. You should thave examined her insides thoroughly after death to discover the cause. It is often caused by cold, by a sunstroke, by indigestion, some say that eating maggotty meat will cause it, a blow on the head, or an abcess in the ear brought on by a draught of air. Try giving the hen a little hyposulphite of soda in water and a pill of assafoetida.

SQUABS FOR PROFITS.

At the present time there are more people going into the squab business than ever before. There is more demand in the market for good squabs now than a year ago, and the supply does not nearly fill the demand. Squabs were higher last winter in the Boston market than ever before. The principal thing to make sure of in the squab business is to have your birds thoroughly mated. This can only be done by careful study. It is almost impossible to control or keep track of every mated pair if they are kept in large flocks. For this reason we advocate lofts of a proper size for about twenty to fifty pairs. The labor will be increased but the returns will more than pay for the extra labor.

The object of every squab breeder is to get the greatest number of squabs per year from every old pair and to do this the birds must be given every opportunity. The proper nesting places are most important. There are certain kinds of nests that pigeons like, and others that they do not; when you read in a book that nests should be all one foot square like empty egg boxes turned on one side and stacked in rows, you can make up your mind that the party who wrote the book has not had as much experience as he might have had. A pair of pigeons should have a nesting place at least three feet long by one foot high and one foot wide. This will allow them a comfortable little home with a nest pan in each end and a space to do their courting in the center. If some good kind of fronts are placed over their home they like it so much the better. If breeders who are now using the egg-box style will throw them out and build new nests after this style, they will learn the difference in short order. If you are using wooden nests throw them out also and buy some good earthen ones, then you will have begun on the right road.

BRAN AS POULTRY FEED.

Bran enters largely into the feeding of some poultry men. Their method of using it is to put it in a box or long trough where the birds, both old and young, can get at it and pick at will. Of course not much will be eaten at one time, and this is what is desired. We have found that chicks especially do not like to make bran their sole diet, and too much of it leads to digestion troubles. One of the best ways to use ground foods, is making a mash of them for feeding either at morning or night. Both plans can be practiced at the same time. The effect of bran is just the opposite to that of whole corn. The corn when fed for a long time alone produces indigestion, while the bran has a loosening effect. Those that are opposed to the use of bran have tried it in too large quantities and have made it a large part of the whole feed. In some cases the poor results with bran have come from the fact that the bran contained a great deal of ground weed seeds, such as corn cockle.

The best science—extracting sunshine from a cloudy way.

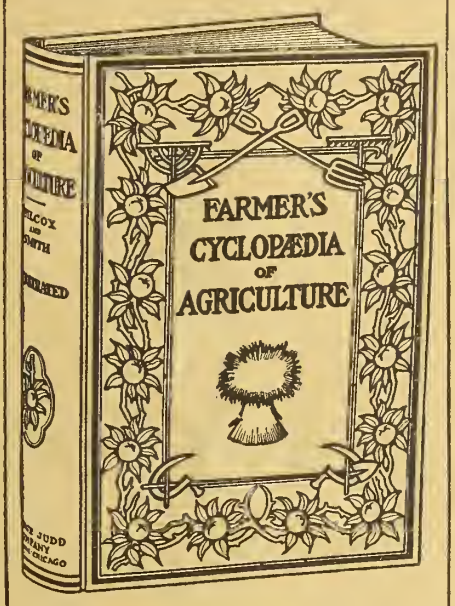
Farmer's Cyclopedia of Agriculture



A Compendium of Agricultural Science and Practice on Farm, Orchard and Garden Crops, the Feeding and Diseases of Farm Animals, Dairy Farming, and Poultry in the United States and Canada

Authors: EARLEY VERNON WILCOX, Ph. D.
CLARENCE BEAMAN SMITH, M. S.
Assistant Editors in the Office of Experiment Stations, United States Dept. of Agriculture

The World Moves

and whoever would not be left behind must lay hold on every means that enables him to move with it. As a basis of one's efforts nothing is more essential than the possession of a good work of reference

Adapted to the Conditions Peculiar to California and Adjoining States

The Farmer's Cyclopedia embodies in its many articles, most of the results of years of painstaking work at the California and neighboring State Agricultural Experiment Stations. It is thus, in effect, both a digest of local and state experience, and a compendium of general knowledge, all of which will prove of indispensable helpfulness to everyone in this section.

The Last Twenty Years of Progress

have measured more changes and recorded more advances in every branch of agricultural science than have been achieved during the hundred years preceding. During all these years no reference book adequately covering the subject has been issued.

The plan of this work is most comprehensive. Every article has received the most careful preparation at the hands of the authors, who have enlisted the co-operation of the highest authorities in the various departments. The greatest educators of the world, representing every branch of agriculture, here unite in one immense faculty to present directly and plainly the pertinent facts of their specialties. Every statement is authoritative and absolutely reliable.

If you wish to know about field crops, garden vegetables, fruits, nuts and other economic plants, farm animals, dairy farming, poultry, also manures, fertilizers, principles of feeding, soils, drainage, irrigation, spraying, veterinary medicines, etc, etc, it is here. Everything concerning farm matters is treated with great thoroughness, though without undue fullness. We claim for it the unique distinction of presenting for the first time, in a carefully arranged and perfectly accessible form, an accurate summary of every subject of interest to farmers, etc.

Over 6000 Topics Indexed
A Wealth of Illustrations

An important part of this work is its very complete and elaborate index, with cross-references under both scientific and common names, so that any information wanted can be found at once. There are between 6000 and 7000 topics covered in these references, making the most perfect index to agriculture ever attempted. It contains 700 royal octavo pages (9½ x 7 inches) and nearly 500 superb half-tone and other original illustrations. Type, paper, printing and binding are all in the highest style of the bookmaker's art, worthy alike of the well-qualified authors, the enterprising publishers, and the industry of agriculture.

PRICE IN HALF MOROCCO, $4.50

To Cultivator readers we make this proposition:—Fill out and sign the enclosed coupon and mail to this office and the book will be delivered postpaid at once and your Cultivator subscription advanced one year.

CUT OUT AND MAIL THIS COUPON AT ONCE

Until the $5 is paid in full title to the Cyclopedia to be vested in you.

NAME.....

P. O.....STATE

—Burbank's Australian Everbearing—
Crimson Winter Rhubarb

Crimson Winter Rhubarb, the latest and best of Luther Burbank's introductions, is a delicious fruit and vegetable full of goodness and profit. It merits the attention of planters everywhere, as it grows luxuriantly under varied conditions. No other crop brings such profitable returns.

We have the most perfect stock in all sizes of plants, from extra large roots to medium and small sizes for acreage planting. Will fill your order for one plant as cheerfully as for a thousand. Write for leaflet or any information.

100,000 Plants Now Ready for Market

Crimson Winter starts to grow vigorously by October and produces stalks continually until after common varieties make their first appearance, some six months later. In our rainless California climate it reluctantly takes a rest during midsummer, but if kept moist produces stalks abundantly at all seasons; it is in fact absolutely perpetual. The stalks are of medium size, averaging twelve to eighteen inches in length, about one inch in diameter, of a beautiful crimson color; when cooked, turning to a clear crimson.

Rhubarb is as easily and cheaply gathered as apricots or peaches; hence at same rate per ton is a much better paying proposition, even the first year, than any deciduous orchard when in its prime. It delights in any good vegetable soil (if not too wet) that produces good crops of onions, sweet potatoes, melons, etc. Excessive heat seems to have no ill effects. The plants we now offer are best size for successful planting and will produce a good crop of marketable stems within three months.

While we make a specialty of Crimson Winter Rhubarb, we also grow the following excellent varieties: Strawberry (or Lorenzo), Linneaus, Myatt's Victoria, Monarch.

Medium size plants, ***Crimson Winter,*** 25c each, $1.50 per dozen, $7.50 per 100, $50 per 1000.

Strawberry (or Lorenzo), Linneaus, Myatt's Victoria and Monarch, medium size, 15c each, $1.00 per dozen, $4.00 per 100, $30 per 1000.

We can supply a limited quantity extra large plants; prices on application. Postage stamps accepted for amounts less than $1.00. Special price on large orders and to the trade.

Queries and Suggestions

LOGANBERRY CANES.

Editor Cultivator: In a recent number of your paper I noticed an article on the care of the Loganberry, which recommended the cutting of all the canes close to the ground as soon as the fruiting season was over, and mulching with about four inches stable manure. My canes are still blossoming and have green and ripe berries. I would like to know how late in the season it would do to pursue that method and have ample time to grow good canes for the next year's crop.—R. A. C., Long Beach.

In Wickson's "Vegetables," it says that Loganberry care and culture is the same as for dewberries. One grower quoted states that immediately after the first rain (usually in October), he cuts the canes down to 16 inches. We are certain that you may safely cut your canes as late as the first rain, but they should not be irrigated in the meantime.

Regarding the different treatment of berry bushes, Mr. Gray, originator of the Gardena dewberry, gave us the following account of a novel experience: "My bushes had scale very bad. I had been cutting them off so as to leave short canes, and of course the scale remained. By accident some berry canes had been cut off below the ground and I noticed that the canes arising were free from scale. Now I plow a furrow each side of every row so that the dirt will bury the canes several inches. They are left in this condition until the scale below the ground are dead. Then the canes are cut off below the soil. The winter rains and subsequent cultivation removes the earth from the row, and thus I keep down the scale." It really seems as if no certain rule obtains and cane may be cut to any height and at any time before the winter rains induce a new growth.

CYPRESS HEDGE.

Editor Cultivator: I should like to know through your valuable paper what to do for a cypress hedge when it begins to die out in spots. Mine is quite a novel hedge, being trained in letters to advertise my business. Yet, in spite of all I can do, it seems to grow brown, finally dying entirely.—S. H. K., Los Angeles.

This "dying out in spots" with our cypress hedges has always been a puzzle to all interested. In the case of two hedges of 15 and 23 years growth (which the writer examined) the roots were in such a close, tangled mass that the whole hedge seemed like one plant. The conclusion reached was that some of the plants were choked to death. These hedges, when supplied with water, grow very vigorously, and in the unnatural condition in which they are placed make an unusual and abnormal amount of root growth, with the result of the "survival of the fittest" only. Hedges should be planted thickly and when the gaps between the plants are well closed, every other plant should be removed; the cypress can be made to cover any distance in lateral growth, even to 30 feet. Your only recourse is to replant.

WINTER CABBAGE.

Editor Cultivator: I intend to plant eight acres of Winningstadt cabbage for winter market in the East, and I want to have them matured by February 15th to March 15th. Will you kindly let me know what month to set out the plants. I am on low damp land, with lots of water.—Geo. Cordell, Long Beach.

In the locality you are in the seed should be sown by September 20th at latest. Use one-quarter pound of seed to the acre. The Improved Quedlinburg strain of Early Winningstadt has given general satisfaction. Last year those who planted later than date above mentioned thought they made a mistake in not planting earler and Mr. Musser, of the firm of Johnson & Musser, recommends not later than September 20th for planting.

CLARIFYING VINEGAR.

Subscriber at Healdsburg who is manufacturing cider vinegar in considerable quantities, has trouble in clarifying it, and wishes help in that direction.

The process of making vinegar for home use, or even for market, is quite simple, the first requisite being perfectly clean vats or barrels. After the juices have been obtained and emptied into the receptacles, dissolve a yeast cake in a small amount of liquid, pour into the mass and thoroughly stir with a clean stick. A strong fermentation will soon take place, which should be allowed to continue undistrubed until it ceases from its own accord. Then procure some "mother of vinegar" and float it upon the surface of the liquid. The rapidity of the transformation to vinegar will depend upon the temperature at which the material is kept. There should be no trouble with its clarifying providing no foreign or adulterant substances are used. We cannot understand why cider vinegar should not be a clarified product.

SPRAY FOR WALNUT BLIGHT.

Editor of Cultivator:—Kindly give me spray for blight of walnut trees.—L. T. Chappell, Walnut Grove, San Jose.

It must be confessed that as yet there is no satisfactory remedy for the blight. The one most usually recommended is the Bordeaux mixture, which has often been given in the columns of the Cultivator. The spreading of a liberal coating of air-slaked lime on the ground underneath the trees is claimed by some to prevent the spread of the spores on next year's growth. The spraying when done with the Bordeaux mixture is usually in the dormant season, or very soon after the leaves start. We believe it would be of slight value at this season of the year.

TOMATO WILT.

Editor of Cultivator:—Noticing in the Cultivator of the 11th an article on tomato wilt, I take the liberty of giving my experience, which may possibly be of interest.

About six weeks ago I had a few nice tomato plants, at that time of good size. I noticed one day that two of them were nearly dead, and others badly wilted so that about six or eight inches of the ends of the branches were drooping. I pruned off the wilted ends, and thinking they would be benefited by loosening the earth, I began to spade, and turned up a great many large grubs. I turned the chickens loose on these and continued the spading, thoroughly cleaning the ground. One plant was about dead and others far gone. But the better ones of them immediately recovered, and today I have thrifty bearing vines and a nice lot of fruit.—J. W. Anderson, San Dimas.

This apparently accomplished good results in the above case, but if Mr. Anderson gets a good straight case of tomato wilt, it will take more scratching than the hens can do to get rid of it.

HOSE AND PIPE FOR IRRIGATION.

Editor of Cultivator:—Will you inform me through your valuable paper where I can obtain information as to hose and pipe for irrigating alfalfa? What size of hose, the length of joints, kind of couplings, and approximate life of the hose. Also can you give me information about building concrete pipe in the trench?—Fred W. Jones, Santa Paula.

The best information regarding canvas hose can be secured by writing W. H. Hoegee & Co., who furnish it ready for use, including couplers and attachments. Regarding movable iron pipe, write the Tallerday M'f'g Co., Doldgeville, California. Their pipe is put up in various sizes, from four inches up, and in ten-foot lengths. Of course the governing factor in the size of pipe or hose will be the amount of water to be conducted. The manufacturing of concrete pipe in the trench is usually accomplished by the use of special machines which we believe are patented. If, however, you mean small pipe, two or three inches inside diameter, these are made by using smooth two or three inch iron pipe for the inner mold. The trench is then dug rather narrow and it makes the outer mold. A layer of the concrete made of five or six parts of fine gravel and sand to one part of Portland cement is packed in the bottom of the trench two or three inches deep, and say five or six inches long. The smooth piece of iron pipe is then laid in the center of this foundation and around it and above it is thoroughly tamped the concrete. It will be well while this is being done to give an occasional slight turn to the pipe to prevent its becoming so thoroughly embedded that it cannot be removed. When a few feet of the pipe is covered it may gradually be withdrawn, a foot or at the most a few feet at a time. Thus continuing to the end of the ditch.

TO CLEAN PEANUTS.

Editor Cultivator:—Kindly inform me how to bleach peanuts for the market. I find that while a dark shell does not hurt the flavor it hurts the selling value.—F. S. J., Custer, Okla.

Where peanuts are grown on a light, sandy soil, the cleaning is given by placing in a simply constructed home-made cleaner. It consists of a cylindrical or barrel-shaped box three or four feet long and two feet in diameter. Slats are nailed to two circular pieces of board and spaced so as not to allow the peanuts to pass through the inter-slat spaces. An axis runs through the box and transverse pieces are fastened to the ends of this axis as to an old style well windlass. A door is made into one side of this box for the admission of the peanuts, and the windlass or crank in being turned rolls and rubs the nuts together, thus freeing them from dirt that may adhere and to some extent polishing the pods. In peanut sections there are factories where the process of cleaning and polishing is done by improved machinery. Of course large plantations have machinery made for this purpose, but for the small planter the home-made machine has proved satisfactory. The discoloration that comes to peanuts from being planted on blacker, heavier soil, may possibly be removed by a liquid dip, but of this we are uninformed, and ask our subscribers who may enlighten the Oklahoma enquirer to send information on this subject.

"Senator," he asked, "have you really any fixed convictions?"

"Not just now," he replied, "but I expect to have one or two shortly after the beginning of the next session."—Chicago Record-Herald.

SHADOW-LAND.

Far from the world that we live in today
Shadow-land lies;
None know how far it is, none know the way,
What are its boundaries no one can say,
Only sunrise;
No one in life has set foot on that shore,
Formed from the wreck of the sad nevermore.

Memory governs this shadowy land,
Reigning supreme;
Ofttimes there come at her word of command
Forms we have known, from the far-distant strand,
Faint as a dream;
Forms of those dear in the days which have flown,
Forms of beloved ones in life's morning known.

With them they bring long-lost scenes of the past
Back to our view;
Pictures of friendships not destined to last,
Loves that grew weak 'neath adversities' blast,
Painted anew;
Ridges and ripples in Time's shifting sand,
Hidden till now in the far Shadow-land.

A Shopping Day.

We met at a hotel and I thought her one of the most charming women I had ever seen.

Refined and almost hyper-sensitive, she struck me at once as being a woman of breeding and distinction. Yet on the few occasions, when, as our acquaintance ripened, I visited her at her smart and elegantly appointed flat, I felt an instinctive aversion to the friends and acquaintances I met there.

Of her people she seldom spoke—her parents were dead, she told me, and her husband was abroad, but might be home again at any time.

She was always exquisitely dressed in the latest fashion, and money seemed abundant with her. She was an adept shopper, quick at knowing what she wanted and quicker still at seeing it and I was very glad when she offered to pilot me through the difficult mazes of the winter sales.

I am not possessed of a large dress allowance, and my wardrobe for the coming season depends somewhat on my successful purchases in sale times. Mrs. Vereker was just the guide to help me through. She possessed such perfect taste that I felt quite safe in her hands.

We sat one evening arranging what we were to buy.

"It is far better to go now when the first rush of the sales is over," said Mrs. Vereker. "I went the first three days myself, but the crowd was awful, and there are still plenty of things to be had."

"Did you pick up many things?" I asked.

She laid down the list she was making and stared at me in dumb amazement. Then her face cleared.

"Yes—no, not very much. Let me see; I bought this tea coat and some hats and my new gray coat—that is all, I believe."

She continued the list, and at last I rose with a sigh of deep relief.

"It's so good of you. We'll go to——first and then on to Bond street"—I glanced at the list—"and get the fur at ———; they can always be relied on to really reduce things. I'll call for you at 9 tomorrow, and we'll get Norman to lend me his motor."

"Yes, do," she said. "I love a motor—we can go to double the number of shops and spend the whole morning looking round until we find exactly what we want."

The next morning I called for Mrs. Vereker and found her waiting.

"Won't you find that coat too hot," I asked as we reached the first of our shops and I slipped off my own heavy motoring coat.

"No, I love it," she replied. "I am never too warm"—and drawing her voluminous skirts across a pavement luckily clean, she swept into the shop with her usual graceful, languid air.

I bought my coat and selected some lace, and went on to——, where I chose a few modest and one or two more expensive blouses, then we went on to a third and last shop. While I was choosing some ribbon in the multi-colored ribbon department, Mrs. Vereker said to me:

"I am just going to the handkerchiefs; I will join you in the fur department—you are going there?"

"Yes; I shan't be long."

"Nor I," she answered; "I am very tired." I had finished my purchases when she came back.

"Are you ready? I am feeling so faint. Do you mind hurrying?"

"I'm just ready," I said, "this very moment," and I put my hand in my muff to get my purse. There was no purse there, and I gave a cry of dismay. "Mrs. Vereker!—my purse!—it's gone!—and I had £25 in it. I had it a moment ago—I must have put it down in the ribbon department."

"Let me pay," she began—but I interrupted her.

"Nonsense, it can't be really gone"—and I almost ran to the ribbon department.

I found the shopwalker and the assistant—but no one had seen it, and baskets of ribbons were hastily searched without result.

"It is very dangerous to lay your purse down in a crowd," said the shopwalker, who knew me well; "it's only a wonder, madam, you didn't lose your muff as well."

I went back disconsolate to the fur department.

"I am so awfully sorry to have kept you," I began, trying not to show my vexation more than I could help. "Are you better?"

She nodded and rose with haste. "Yes, but let's go, if you don't mind. You can come back again and make inquiries. It doesn't matter about your purse. I have heaps of things and bits of fur I do not want.

"Nonsense," I said, "as though I should take yours."

"But, my dear child, I have so many, and surely a married woman can help a girl; besides, I dare say the purse will turn up.

"Pardon me, madam."

A grave looking man in a frock coat slid past me and laid his hand firmly on Mrs. Vereker's arm at the moment she was stepping into my motor.

"What is it? This lady has left all information about her purse." She moved her arm haughtily.

The man's face grew graver.

"Perhaps you will kindly come back with me. It's you we want, if you please, madam."

There was a faint sneer on the word "madam," and Mrs. Vereker's face blanched.

"What do you mean?" she stammered. "How dare you? Cannot you see I am ill and wish to go home at once?"

I sprang to her side. "Never mind about the wretched purse," I said to the man. "This lady is not well; let her go home and I will come back about the purse."

The man took no notice of me, but bending to Mrs. Vereker said something that made her step suddenly back and stand by his side. Then to my utter amazement, shaking obviously from head to foot, and without even looking at me, she turned into the shop and I followed in bewildered dismay.

It was soon over. A few minutes in a private room and two female searchers had taken the heavy coat, far heavier now with the lace and furs and flowers and blouses that were marvelously fastened in its ample folds. Under her cloak and attached to her waist by firm hooks hung several furs and many pieces of costly lace.

Mrs. Vereker, white as death, showed no sign of what she must be feeling, but looked in front of her with a dazed, set face, while I slipped outside to the waiting man. He was talking to another shopwalker, who, luckily knew me well.

"What is it?" I asked. "Is she a thief?"—a silly question he answered at once.

"One of the worst shoplifters in London," he said laconically, "and yet we've never been able to catch her. Her husband is doing six months now for the very same thing. She knew you were known here, madam, and brought you to shield her."

"But how did you find her out today?" I asked, aghast, "and what did you see her take?"

"Something that belongs to you," he said, as he gravely handed me my purse.—R Neish in London Daily Mail.

Do not think yourself educated if you cannot keep your temper, if you have not learned to be kind and to bear patiently with the faults of others. It is a good thing to be able to construe a Latin sentence or work a difficult problem in algebra, but how trifling such things are compared with training in gentleness and courtesy and manhood! Unless the heart is educated, as well as the head, your education is only begun.

Love and a cough cannot be concealed.

A POSY FOR THE BREAKFAST TABLE.

If you have the least bit of a garden or even a few shade trees to draw on, don't neglect to have a fresh posy or cluster of pretty leaves on the breakfast table. Even a confirmed hypochondriac must find his day grown brighter with a newly opened morning glory smiling into his face. Four or five morning glories, with their curling tendrils climbing over a slender vase in the center of the table are an incentive to holy living. A dainty purple or white aster, a gay nasturtium or bit of scarlet salvia ready to tuck into the buttonhole will carry sunshine with it to store or school or dingy office.

THESE SHOULD NOT MARRY.

The woman who expects to have "a good easy time."

The woman who wants to refurnish her house every spring.

The woman who thinks that cook and nurse can keep house.

The woman who would die rather than wear last season's hat.

The woman who expects a declaration of love three times a day.

The woman who marries in order to have someone to pay her bills.

The woman who thinks she can get $5000 worth of style out of a $1000 income.

The woman who proudly declares that she cannot even hem a pocket handkerchief and never made up a bed in her life.—Philadelphia Record.

HELP!

Settle Your Own Country

The Santa Fe

is doing its share in trying to send more farmers to your country. You can help that work by a little effort.

Every reader of this notice is requested to send to the undersigned a list of his friends in the East who may possibly be interested. Literature regarding your country will be mailed to them, and any questions they ask will be fully answered.

THE SHEARING.

The day they cut the baby's hair
The house was all a-fidget;
Such fuss they made, you would have said,
He was a king—the midget!

Some wanted this, some wanted that;
Some thought that it was dreadful
To lay a hand upon one strand
Of all that precious headful.

While others said, to leave his curls
Would be the height of folly,
Unless they put him with the girls
And called him Sue or Molly.

The barber's shears went snip-a-snip,
The golden fluff was flying;
Grandmother had a trembling lip,
And aunt was almost crying.

The men folks said, "Why, hello, Boss,
You're looking five years older!"
But mother laid the shaven head
Close, close against her shoulder.

Ah, well; the nest must lose its birds,
The cradle yield its treasure;
Time will not stay a single day
For any pleader's pleasure.

And when the hour's work was weighed,
The scales were even, maybe;
For father gained a little man
When mother lost her baby!
—Nancy Byrd Turner, in St. Nicholas.

THE EXILE OF CAESAR.

Caesar was a large St. Bernard dog that lived on a small island. From one end of the island to the other and all around it several times a day was no more exercise than Caesar needed to keep him from getting fat and dull. So he was to be seen often bounding and leaping over the island, taking his constitutional. Of course, living on an island, he was a great sailor and dearly loved going out with his master or any of the others. His master had charge of the oyster beds that were the property of the owner of the island and part of his duty was to see that no one stole the oysters that were waiting to be shipped to the city markets.

One day his master brought a tiny, fluffy little ball of a dog home with him from the city. Caesar looked at the newcomer with scorn and curiosity, but after an exchange of low toned remarks on his part and little sharp ones on the part of the small dog they decided to be friends and for the rest of the summer they were to be seen going about together, Caesar large and imposing, the little dog looking hardly more than a toy. When they lay down for a nap together Caesar would make a semi-circle of his huge body and the little fluffy dog would lie inside the semi-circle with his two little front paws resting on Caesar's big one.

When the summer was over, Caesar had to go with his master's family to the city to live. He had always lived on the island and had enjoyed his freedom there. He seemed to know that he was going to a less congenial place and when he went aboard the boat is was not with his customary alacrity and joy.

When they arrived at the city dock, he refused to come out from the cabin to which he had retreated. They coaxed and threatened, but Caesar staid within. At last his master put his hand and took hold of Caesar's leg. The big dog bit him till the blood came. "Oh, Caesar, how could you?" cried his master, reproachfully, and then when Caesar heard his master's voice and looked out and saw that he had hurt him he was so repentant that he came out and licked the wounded hand, whimpering and begging for forgiveness. He still refused to get off the boat however, until they turned it over so that the water came in, flooding him out. Then he swam ashore.

Sadly he went to his new home on land. His master lived in a flat and the yard was hardly big enough for him to turn around in. His appetite and spirits failed and his master saw that unless something was done he would die of homesickness.

He went, therefore, to the man who had taken his place on the island and asked him if he would buy Caesar, naming a low price at which he would sell him. The man said he would, for he wanted just such a fine, big dog to help protect the oysters against thieves. So Caesar went back to the island, and never was there a dog so glad to get home as he was to return to the island. He ran about sniffing and barking with delight and then rolled over and over with joy.

HOMELY HINTS.

To prevent a conflagration when a lamp has been overturned apply earth, sand or flour to have the desired effect and stop the spread of the flames.

A stove daily rubbed with a newspaper will retain its blacking much longer.

To make varnish dissolve a pound and a half of shellac in a gallon of naptha. Add a small quantity of dragon's blood to give it a good color.

Glue that is both damp and waterproof is easily made. Take ordinary glue, soak it in water till quite soft, then put it in a jar with a little linseed oil and stand on the stove till melted.

That rusty flatiron should be rubbed over with beeswax and lard.

To make a furniture oil take half a pint of linseed oil, half a gill of spirits of wine, half a gill of spirits of salt. Shake the bottle before using and rub on with a piece of linen.

Kerosene oil will remove finger marks without taking paint or varnish as well. It also helps to clean bath tubs and basins.

A soft chamois wrung from tepid water is good to dust fine furniture or wood work.

It is said that a bit of camphor gum put in your silver chest will help to keep the metal bright.

Salt or Indian meal will brighten the carpets and keep the dust from rising.

Whiting and olive oil mixed to a paste will remove rust from nickel.

Ivory handles of knives and piano keys will preserve their creamy tone if wiped off twice a week with a cloth dampened with alcohol. If discolored a little whiting and spirts blended may be applied with a bit of flannel. Dry with chamois.

"A little hope, a little faith serene,
A little word of strength for those who fall,
A litle smiling, tho' tears come between,
A little charity if need should call—
And O! not paltry is our life, nor small,
But big and fine with sweet delight,
If that we keep, each for the sake of all,
These little things in sight."

To look back with pleasure on our past life is to double it.

Beware of the silent dog and the still water.

He who has property in the soil has the same up to the sky.

Cookery Recipes

Editor Cultivator: Seeing your request in Cultivator for good cooking recipes, send in a few of my own, which I know to be good:

Snow Mountain Cake.—Cream one cup butter, 2 cups of sugar, very fine; add whites of eight well beaten eggs; one cup of sweet milk, four cups of flour, into which sift two large teaspoons of baking powder; flavoring to suit. Bake in layers; chocolate or caramel filling.

Chocolate Cream.—Half a cake of chocolate dissolved in a little hot water; put in a cup of sweet milk and when it boils have five eggs well beaten and mixed with two cups of milk; pour the hot chocolate into the eggs and milk; stir well and boil all together for a few minutes; sweeten to taste; set on ice.

Plum Pudding.—One cup suet, 1 cup sweet milk, 1 cup molasses, 1 cup sugar, 1 cup currants, 2½ cups raisins, 4 cups flour, 1 teaspoon cloves, 1 teaspoon cinnamon, one of spice, one of soda; put in a cloth bag and boil 3 hours. Serve with brandy sauce.

Fruit Blanc-Mange—Stew fresh blackberries or fresh peaches, strain off the juice and sweeten to taste. Place over fire in a double kettle until it boils. While boiling, stir in corn starch wet with a little cold water, allowing 2 tablespoons of starch for each pint of juice. When thick pour into moulds wet in cold water, set away to cool. To be eaten with cream and sugar.—Mrs. E. C. D., Santa Rosa, Cal.

* * *

Saratoga Chips.—A southern house keeper, celebrated for her excellent Saratoga potatoes, describes her method. It is the familiar one, with one variation. After the potatoes are sliced as thin as shavings, they are thrown into cold water until crisp. Turn this water off and pour on boiling water for an instant. This takes out all the starch. The cold water should be turned on again quicly, and left until the slices are crisp. Wipe dry and fry, a few pieces at a time, in frying basket.

* * *

A Delicious Picnic Dainty.—Hard-boiled eggs and sardines may be appetizingly united in preparing a dish suitable for picnics or lawn fetes. Remove the yolks and mash with the fish to form a smooth paste, adding a little lemon juice and salt. Fill each half of the white with the mixture, join them together and serve on lettuce or cress.

* * *

Filling—Place one-half pound of figs and one cupful of stoned raisins in a steamer and steam thirty minutes. While hot chop fine; add one teaspoonful of vanilla, two-thirds of a cupful of sugar and the beaten whites of three eggs.

* * *

Macaroni with Codfish.—Soak half a pound of codfish over night in cold water. Remove the bones and skin. Break macaroni into small pieces and boil until tender. Steam the codfish half an hour. Arrange on a plate a layer of fish and a few slices of hard boiled eggs, then a layer of macaroni and then fish. Make a white sauce with one tablespoonful of butter and one of flour. Stir over the fire until smooth and boiling. Season with salt and pepper. Pour this boiling sauce over the top of the macaroni; sprinkle chopped parsley over the top and serve.

WHAT TO SERVE.

Celery sauce with quail.
Walnut catsup, with venison.
Mint sauce, with roast lamb.
Apple sauce, with roast pork.
Currant jelly, with roast goose.
French dressing, with sardines.
Orange salad, with roast chicken.
Cream sauce, with sweetbreads.
Sauce piquante, with baked shad.
Apple sauce, with pork croquettes.
Sauce tartare, with boiled lobster.
Tomato catsup, with corned beef.
Melted butter sauce, with mackerel.
Tart grape jelly, with canvasback duck.
Chicken croquettes, with sauce tartare.
Maitre d'hotel sauce, with steamed oysters.
Celery and onion dressing, with roast duck.
Olives stuffed with peppers, with fishballs.
Horseradish and fried onions, with liver.
Olives stuffed with cheese, with cold tongue.
Parmesan cheese, with beef and veal sausage.
Oyster and chestnut dressing with roast turkey.
Cream gravy, strawberry preserves, with fried chicken.
White sauce, hard boiled eggs and parsley, with salmon.

When writing advertisers mention Cultivator.

The weather and crop conditions for the week ending August 23, are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

* * *

General Summary.—Nearly normal weather conditions prevailed during the week, with frequent fogs in the coast districts and clear and warm weather in the interior. A thunder storm occurred in Sacramento and vicinity Sunday night, accompanied by light rain.

Grain threshing and hay baling are progressing in some sections and completed in others. The grain crop is almost a failure in some places and fair in others, while in a few places it is reported quite heavy. The barley crop averages better than wheat in nearly all sections, and oats are very light. Hay is of excellent quality and the yield is the best for several years. Hops are advancing satisfactorily and in many places give promise of more than an average crop. A large crop of sugar beets is being harvested and the beets have a high percentage of sugar. Beans, corn, potatoes and garden vegetables are doing well. Dry feed is still plentiful in most sections and cattle are in good condition. Irrigation water is holding out well in the central and southern districts.

Although grapes in some sections were considerably injured by extreme heat during July and August, the prospect is still good for an excellent yield of most varieties. Raisin grapes are rapidly maturing and picking has commenced in some vineyards. Muscatels, Sultanas and other varieties of table grapes are plentiful in the markets and shipments are being made to eastern markets. Deciduous fruit harvest is progressing and canning and drying continue. Walnuts and almonds are making good growth. Citrus fruits are in excellent condition in all sections and the prospect is good for a record-breaking crop.

* * *

Eureka Summary.—Foggy mornings, but past week generally favorable. Worms doing much damage to vegetables in the Arcata bottom. Peaches are poor. Apples about an average yield; quality of early varieties fair. Harvesting oats rapidly.

* * *

Los Angeles Summary.—Beans doing well under favorable weather conditions. Threshing continues; yield good. Some shipments made. Mountain pasture excellent. Meadow hay being cut. Some thunderstorms in the mountains.

HOW IT LOOKED.

"Dear John," wrote Mrs. Newlywed from the shore. "I enclose the hotel bill."

"Dear Jane, I enclose cheque," wrote John, "but please don't buy any more hotels at this price—they are robbing you."

AN AD-VANTAGE.

He who would add unto his trade
Should have an "ad" and well displayed.
For "ads", if one knows how to write 'em,
Add to one's trade ad infinitum.

Los Angeles Markets.

Los Angeles, August 23, 1905.

Butter.

B. of T. Creamery	57½
Valley Creamery, fancy	55@57½
Coast Creamery	47½@50
Fancy Dairy	45½@47½
Cooking, per lb	17@18

Cheese.

Cal. 3-lb. hand	14¼
Cal. Young America	15¼
California Anchor	14¼
Northern	12½@13
Eastern	16
Domestic Swiss	16½
Imported do	27½

Eggs.

Eggs remain the same as last week and receipts still continue light.

Eggs, fresh ranch	29@30
Eastern and Storage	25@26
Seconds	21@22

Poultry.

Poultry about the same as last week. Turkeys, live, at sixteen to eighteen cents, while dressed stock commands from twenty-three to twenty-four.

Fryers, 2½ lbs	13@14
Broilers,under 2 lbs, per lb	13@14
Young Roosters, per lb	13@14
Hens, per lb	12
Ducks, per lb	10
Turkeys, per lb	16@18

Cocoanut Meal	1.55

The beds or sheds for young pigs should always be arranged so the pigs can have the full benefit of the sun's rays.

San Francisco Markets.

San Francisco, August 23, 1905.

Dairy.

The best grades of creamery butter have advanced a cent over quotations of a week ago. These prices have been well maintained and available parcels of the favorite brands have been closely cleaned out of the first hands. There is a good buying interest displayed on the cheaper sorts.

BUTTER—Per lb:

Creamery, fancy	25 @26
Creamery, good to choice	23 @24
Dairy, choice	20 @22
Store	17 @18

CHEESE—Per lb:

Cal. Creamery, mild new, ex.	12 @13
Do, choice	9 @10
Young American	12 @13
Eastern, N. Y. Cream	15 @16

Eggs.

Ranch eggs have been in light demand but have ruled steady at the old prices under light supply. The best selections of whites have secured the maximum rates.

Ranch, selected large	32 @33
Ranch, good to fancy	28 @30
Store	18 @23
Eastern, extra	24 @25
Eastern, firsts	21 @23
Eastern, seconds	18 @20

Poultry.

Young poultry has advanced slightly since last quotations, but at this time the market is in free supply, heavy receipts arriving from near by points and the market weaker in tone.

POULTRY—Old Roosters, per doz., $4.50@5; young Roosters, $5.50@7; Fryers, $3.50@4; Broilers, $2@3; Hens small, $4@5; large, $5.50@6.50; Live Turkeys, per lb., 19@22c; Spring Turkeys, 23@25c; Ducks, old, $4@4.50; young, $4@6; Geese, per pair, $1.75@2; Goslings, $2; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $1.50@$1.75.

Fresh Fruits.

Apples, per box, fancy, 85c@$1.15; common to choice, 40@75c; Crabapples, per small box, 60@75c; large, $1.40@1.75.

Figs—Per box, Black, 50c@$1, as to size of package; White, 40@65c.

Pears—Per box, Bartlett, 75c@$1.50; bulk, per ton, nominal; other varieties, per box, 50c@$1.

Peaches—Per box, Mountain, 50@85c; carriers, 40@80c; open boxes, 60c@$1.50; bulk, per ton, $30@50.

Plums and Prunes—Per small box or crate, 50@85c, as to variety; open boxes, 40c@$1.

Quinces—Per box, 50@75c.

Grapes—Per box or crate, Seedless, 60@85c; Sweet water, 50@75c; Muscats, 60c@$1; Blacks, 60c@$1.

MELONS—Cantaloupes—Per crate, River, $1@1.25; Watermelons, per doz., $1@3.50; Nutmeg Melons, 50@75c.

BERRIES—Blackberries—Per chest, $1.50@3.

Raspberries—Per chest, $7@9.

Strawberries—Per chest, Longworths, $8@9; large varieties, $4@6.

Huckleberries—Per lb., 6@7c.

Vegetables.

VEGETABLES—Tomatoes, per box, 75c@$1.25; Green Peppers, per box, Chile, 25@50c; do, Bell, 35@50c; Okra, per box, 50@75c; Garden Beans, per lb, Green, 1@2c; do, Wax, 1½@2½c; Lima, 5@6c; Garden Peas, per lb, 3c; Cucumbers, per box, 25@35c; Summer

Squash, per box, 35@50c; Egg Plant, per box, 50@75c; Garlic, per lb., 5c; Green Corn, per sk, 50c@$1; per crate, $1@1.25.

POTATOES—Per ctl.: River Burbanks, 50@70c; Salinas Burbanks, 90c @$1.15; Early Rose, nominal; Garnet Chile, 40@50c; Sweet Potatoes, $1.25 @$2.25.

ONIONS—Per sk, Yellow, 70@90c.

Dried Fruits.

Apricots and peaches are attracting lively buying interest and the recently advanced rates are firmly held. It is reported that some packers have sold peaches short. Prunes are firm at current rates and offerings find ready market.

DRIED FRUITS—Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb, as follows:

Apples—Evaporated, 1905 crop, fancy, 7½c; choice, 6¾@7c; standard, 6¼@6½c; Sun Dried, nominal.

Peaches—Crawford, fancy, 8¾c; choice, 8@8¼c; standard, 7¾c; Muirs, fancy, 9¼c; choice, 8¼@8¾c; standard, 8c.

Prunes, 1905 crop—Sack basis, f. o. b., for boxed goods add ¼@½c; four size basis, 3¼@3¾c; old crop, 2¾ @3c.

Apricots—Royal, fancy, 8¾@9c; choice, 7¼@8¼c; standard, 6¾@7c; Moorpark, fancy, 12c; choice, 8½@10c.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c; choice, 3¼c; standard, 2¾c; ungraded, 3½c.

Honey and Beeswax.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@ 6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

Hops.

The price of desirable old crop is nominal at 15@20c per lb., according to quality, new, 1905 crop, 14@16c.

Beans and Seeds.

BEANS—Prices per ctl. for sound selections; Large White, $2.75@2.90; small do, $3.50@3.75; Pea, $3.25; Limas, $5.50@5.75; Red, $6.50@8; Pink, fancy, $3.65@3.90; recleaned, ordinary to choice, $2@2.50; Bayos, $4@4.50; Blackeyes, $3.75@4.25; Red Kidneys, $4@4.50. Rain damaged lots of all descriptions offering from 50c@$2 a ctl. below foregoing figures, according to condition.

Live Stock.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@ 5½c; rough heavy, 4¼@4½c; common, 3½@4c.

Hay and Feedstuffs.

HAY—Per ton: Wheat, $7.50@13.50; Wheat and Oat, $7@12.50; Oat, $6@ 11; Barley, $6@9; Clover, $7@10; Alfalfa, $6@9; Stock, $5@6.

New Crop—Wheat, $9@13.50; Oat, $7@11; Wheat and Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@ 24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $21.50@22.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $21.50 @22.50.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@28.50.

Flour and Cereals.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70 @4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.35@$1.42½ for new crop; old higher; White Milling, good to choice, $1.45@1.55 for new and $1.60@1.65 for old.

BARLEY—Choice, No. 1 Feed, $1@ 1.05; some fancy up to $1.06¼; off grades, 97½@98¾c; Shipping and Brewing, $1.05@1.10; Chevalier, $1.10 @1.25.

OATS—Good to choice White, nominal; Red, $1.20@1.40 for new crop; Black, for seed, $1.40.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.40@1.45; small do, $1.55@1.62½; White, $1.37½ @1.42½; Eastern, Yellow, $1.40@ 1.42½; White, $1.40@1.42½; mixed, $1.40.

RYE—Good to choice, per ctl., nominal; new, $1.47½@1.50.

CITRUS MARKETS

Citrus fruits in the eastern market probably reached flood tide for the year last week. Carload after carload of oranges sold in the New York market for exceeding $2000 in price. Old Mission Valencias sold as high as $2400 per car, while a car of Golden Rule Valencias sold by the Exchange grossed $2311 and another grossed $2201. Twenty carloads of oranges and three carloads of lemons were sold during the week as compared with fifteen cars of oranges and two of lemons the corresponding week last year, when prices were fully $2 per box lower than now.

This shows the market to have been in phenominally good condition. As there is little fruit yet to go between now and the first of November, these prices may be again reached but will hardly be exceeded. Lemon prices were also skyward and with very few foreign lemons to come in till October and the California crop nearly exhausted, high prices will in all probability be the rule for some time.

This week the prices have not been quite as good as last week, although demand continues very active and as the same grades have not been offered, it is hard to make comparison. Fruit of second grade has been sold very high and the trade believes it has reached its limit.

New York.

On Tuesday seven cars of citrus fruit, mostly Valencias, were offered at auction. Fancy grades averaged from $5.10 to $6.50, while choice sold from $3.40 to $6.00. A car of Isis, extra fancy, sold for an average of $4.86 per box; La Mesa, extra fancy, sold for $5.09, while a car of extra choice from Highgrove averaged $3.37½. A car of standards from Monrovia brought $3.50 on an average, and a car of choice from Rialto sold for $4.19. Another car of choice, from Riverside, sold for $4.65.

Mediterranean Sweets sold from $3 to $3.80. Fancy grapefruit brought $9.25 per box, the highest price during the season.

Nine cars were sold at this market Tuesday, the largest sale so far this month. Fancy grades of Valencias sold for $4.35 to $5.00 per box. Choice brought from $4.00 to $4.65 and standards from $3.40 to $4.20.

Six thousand boxes of Sicily lemons, generally in good condition, brought, for fancy 300s, $6.60; choice 300s, $5.85; fancy 360s, $6.10 and choice 360s, $5.60.

Seven cars were offered at the auction Wednesday. Fancy Valencias brought from $4.15 to $6.70; choice from $2.65 to $5.80. Fancy Med. Sweets sold at an average of $3.95.

One car of lemons from the Arlington Heights Fruit Co. sold for record prices, extra fancy selling from $7.87½ per box; fancy, $6.65 and extra choice, $6.62½.

Boston.

Two cars of citrus fruit were sold in this market Monday. One car of Valencas brought from $4.50 to $6.15 per box. The other car being lemons, averaged $5.25 per box for fancy.

On Tuesday three cars of citrus were sold. Extra choice Valencias brought $5.40 and choice $4.70. One car of Jaffas, choice, brought an average of $5.30 per box.

Fancy grapefruit sold for $4.00; standards, $2.55.

Philadelphia.

This market has been very strong and but little fruit offered. Tuesday one car of extra choice California lemons were sold at an average of $5.65 per box.

Chicago.

The demand has been very fair. The market is firm on lemons, with plenty of fruit offered. Prices for California fancy lemons, 300 to the box, $7.00 to $7.50; 360 to the box, $7.00 to $7.50; 210 to 240 in boxes, $5.50 to $6.00.

Not many oranges have been in the market. Prices have been rather high, but there is fair sale, Valencias bringing, regular sizes, $5.00 to $5.50; large sizes, $4.25 to $4.50.

CITRUS SHIPMENTS.

Total shipments for the season to date have been 28,769 cars, of which 2772 were lemons.

Fresh Fruit Sales.

Heavy shipments to the East by the California fruit distributors of Sacramento have continued this week. Reports of sales indicate that the market is easier in Boston but is still strong in New York. Other points are averaging slightly below last week. The sales of last week and those of the week before were phenomenal, cars selling from $1100 up to $2200. These prices will in all probability not be again duplicated this season, though the prospects are for good prices for some time to come.

To show what the strength of the market this week is, we quote Tuesday's sales at New York, as follows:

Susquehannas, 85c to $1.70; average, $1.20; Crawfords, 75c to $1.40; average, $1.20; Orange Clings, $1.30 to $1.50; average, $1.42; Elbertas, 85c to $1.80; average, $1.35; Bartletts, $1.35 to $3.25; average, $2.70; Malagas, $2.50 to $2.60; average, $2.52; Giants, $1.05 to $2.20; average, $1.55; Hungarians, $1.55 to $2.30, average, $1.85; Kelseys, ripe, 55c to $1.75, average $1.15.

In Boston the auction results were as follows: Bartletts, $1.15 to $3.80, average, $3.20; Malagas, $2.20 to $2.65, average, $2.25; Late Crawfords, 60c to $1.70; average, $1.32; Susquehannas, Early Crawfords, Orange Clings, 65c to $1.65, average, $1.05; Albright, 85c to $1.25, average, $1.10; Yellow Free, 60c to $1.15, average, 90c; Kelseys, $1.00 to $1.75, average, $1.25; Tragedy, $1.10 to $1.60, average, $1.40; Hungarians, $1.35 to $2.65, average, $1.65.

California Dried Fruits.

NEW YORK, Aug. 22.—The market for evaporated apples is unchanged, with a firm feeling; common to good, 4½@6; prime 7¼; choice 7½ and fancy 8. Prunes are unchanged, from 4¼ to 6½, according to grade. Apricots show no fresh feature, with choice quoted at 8@8¼; extra choice, 8; fancy 9½@10. Peaches are quiet, with fancy quoted at 11½. Raisins are scarce, and prices show an advancing tendency. Loose muscatels are quoted at 4¾@6; seeded raisins 5½@7½, and London layers $1.00@1.15.

IN WOMAN'S BREAST

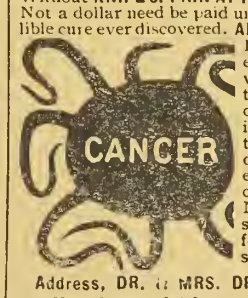
ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

THREE PHYSICIANS OFFER $1000

If They Fail to Cure Any Cancer

Without KNIFE or PAIN AT HALF PRICE for 30 days. Not a dollar need be paid until cured. Only infallible cure ever discovered. ABSOLUTE GUARANTEE.



Best book on cancers ever printed, Sent FREE with testimonials of thousands cured without a failure. A Pacific island plant makes the cures. Most wonderful discovery on earth. Small cancers cured at your home. No X-Ray or other swindle. Write today for our 130-page book, sent free.

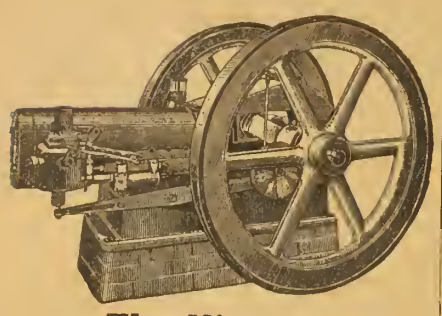
From Los Angeles Times, Wednesday, August 16, 1905:



The Western Gas Engine

LOCAL FIRM GETS PLUM.

Western Gas Engine Co Given Contract for Motor Machinery at Yuma Dam.

Complimentary to Los Angeles and Southern California, as recognized factors in the manufacturing field, the New York Engineering Company, which has the $800,000 contract for constructing the government's reclamation project above Yuma, has determined to use gas instead of steam in the immense work of water excavation at the Yuma damsite, and has ordered nine Los Angeles-built engines for that purpose from the Western Gas Engine Company of this city.

The supervising engineer of the New York concern, C. G. Young, intended to utilize steam in this pump work, but during a recent visit in Los Angeles he was convinced by tests that the gas engines manufactured by the local firm named would be far more advantageous than steam engines, both in power and economy. This recognition by New York of Southern California's machinery-manufacturing ability is keenly appreciated here.

NOTE.—The above news item chronicles the greatest victory every achieved by a California manufactured product. When the most famous expert engineers of this country, and in fact in the world, declare the Western to be the most reliable, substantial and economical power for this most important work, in preference to all other gas engines, East or West, and even in preference to steam, it puts a certain value upon the Western Gas and Distillate Engine that should make it the exclusive choice of every user of power. Numerous other gas engines recognized in this market and known to these engineers, were not even considered, on account of their known unreliability.

Much of the work will be done with steam, as we were unable to furnish within the time specified all of the engines wanted, but these nine, most of them of large size, will all be delivered within 30 days from the receipt of the order. These engines will be run with California No. 2 distillate.

Pumpkins Growing Between Young Grape Vines in the San Joaquin Valley.

PUMPKINS AS A STOCK FOOD.

The above cut is very typical of a pumpkin patch in California. Here grows bigger fruit of this kind than anywhere else in this country. We have seen specimens that weighed two, three and even five hundred pounds each. Stock of all kinds relish the pumpkin and growers make good profit from the land devoted to raising them.

CIRCULATION EXCEEDING 10,500

The Southern California Fruit Exchange

MAIN OFFICE: ROOMS 802-3-4 H. W. HELLMAN BLDG., LOS ANGELES

During the Past Year:

The Exchange has marketed 14,200 cars of oranges and lemons at an average price per car net f.o.b. California, every car included, of over $500, which is over $100 per car more than was received for Exchange fruit during the previous year.

The Exchange obtained the $1.00 rate on lemons continuous throughout the season, which saves in freight to lemon growers, $65.52 on every car shipped.

The Exchange, taking advantage of conditions as they existed in February, started a campaign of advertising our California lemons, of which this State had a large crop this year, with the result that the best prices in the history of the lemon industry have prevailed during the last 100 days. Not realizing our purpose in this lemon campaign, we were most severely criticised by our competitors when we entered upon it, although the wisdom of our action is now clearly apparent to all.

The Exchange sent Jos. H. Call to Washington to appear before the Senate Committee of Inter-State Commerce in the interest of governmental control of railroad rates and private car lines.

The Exchange, through a committee, appeared before the State Board of Trade at San Francisco and obtained the passage of a resolution against reciprocity treaties in place of a proposed resolution in favor of such treaties.

For the Year That We Are Just Entering Upon:

The Exchange has obtained an adjustment of the required minimum in citrus fruits according to the length of the car, thus preventing the overloading of short cars, which practice has caused in the past immense losses from decay to the owners of the fruit.

The Exchange has purchased boxes for the ensuing year at a reduction of around 1½c each, saving to the growers more than $5.00 on each car of fruit shipped, amounting on our business to nearly $100,000 annually. Non-exchange growers, as well, will benefit in this reduction in price on boxes, unless their packing is handled at a fixed price per box, in which case the packer, and not the grower, will get the benefit of the reduction.

The Exchange will continue the fight against reciprocity treaties, hoping thus to prevent any reduction in the duty of 1c per pound on citrus fruits which we now enjoy.

The Exchange has already employed Jos. H. Call to appear in the new investigation of private car lines that has recently been ordered by the Inter-State Commerce Commission.

In all matters affecting the citrus fruit industry the growers can, in the future, expect the **Southern California Fruit Exchange** to take the lead in their interest, as it has in the past, and, in many instances, to fight the growers' battles alone, unaided by other shippers.

Until those who criticise the Exchange can prove to the growers that they have in the past looked after the growers' interests better than has the Exchange, their arguments, made clearly for the purpose of creating dissatisfaction, from which the speculator shippers expect to gain personally, can have but little weight.

The Southern California Fruit Exchange has nothing to conceal and invites a close inspection of all its transactions by those interested, either through its Los Angeles office, or through its various branches in the shipping districts.

Owing to the addition to our holdings of large blocks of fruit in Central and Northern California, in order that we may not be considered sectional or local, our Board of Directors has deemed it advisable to operate after September 1st underthe name of

California Fruit Growers Exchange

A Huge Dam Being Built in Wyoming

A Description of One of the Big National Irrigation Projects, by Guy Elliot Mitchell.

A quarter of a century ago the home of the buffalo, and later a cattle and sheep pasture, with an occasional ranch house, the Big Horn Basin in Wyoming is now the scene of a great activity incident to the building of one of the largest of the government irrigation works. Some years ago Colonel Cody, better known as Buffalo Bill, made a survey of the Shoshone canyon, and in connection with General Miles projected a company to construct a dam and irrigate some 60,000 acres. The necessary capital, however, was not forthcoming, and when the national irrigation law was passed, the government took up the proposition and a large party of engineers has since been employed on the preliminaries of a great work of desert reclamation.

The Shoshone river dashes down a narrow canyon, with jagged and perpendicular walls, and at its narrowest point the government has begun the construction of the highest dam ever built. It will cement together the two canyon walls for 240 feet about the stream bed and its foundation will go below the water line 88 feet additional, down to the solid bed rock. The stream, where it passes between these granite canyon walls, is but 65 feet wide and the dam will form a great lake of 5,000 acres, with a watershed of 1250 square miles, storing enough water to irrigate 150,000 acres, through seven miles of 14-foot tunnels bored in the solid rock.

* * *

No Chance for Land Grabbing.—This will cost about $25 an acre, to be paid back to the government by the settlers under the business-like provisions of the irrigation law. The land itself is free under the homestead act and has been reserved by Secretary Hitchcock from entry under the Desert and other land laws not requiring actual residence and home building.

Few such picturesque and wildly beautiful scenes can be found as this Shoshone canyon. The river is a succession of foaming, rushing rapids, the water coursing along in a deep green flood, and then boiling over great rocks and boulders in a white surge. Only for a few hours each day can the sun find its way to the bottom of this deeply cut gorge, the mountain sides towering into the clouds two and three thousand feet. From above the dam site as one looks down at the engineers working on the foundations, directly underneath, they appear like mimic men.

* * *

Great Forces of Nature.—This Shoshone canyon and its surrounding mountains are one of nature's great handiworks. All has been cut out by the silver stream, rushing in its bed below. For countless ages it has eaten its way through granite and limestone, wearing, wearing, wearing away. For centuries and ages it has flowed, ceaselessly and likewise uselessly on its way to join the flood of the Missouri; now it is to be harnessed and made to produce for man. A thousand farmers will make prosperous homes for themselves and families and raise an annual product of a couple or three million dollars.

Shoshone Dam Site, Jeremiah Ahern, Supervising Engineer U. S. Reclamation Service, in Charge.

In the canyon proper the great forces of nature have wrought wonderfully. Enormous granite boulders have detached themselvse from the mountains and rolled down thousands of feet, crashing their hundreds and thousands of tons into the rocky gorge. Here the river continually plays upon them, searching out the seams and splitting them up or wearing them away and polishing them smooth.

* * *

The Rock Pile of the World.—In the canyon's middle, below the dam site, the jungle of rocks in the narrow river bed appears as though a thousand blasts of giant powder had rent the mountain sides and tumbled every rugged projection into the depths below. The imperishable granite, gray, pink, and vari-colored, oldest of the geological formations made by the welding of various substances when the globe was a molten mass; the later limestones and black volcanic rocks, conglomerates also melted by great heat, the hard red sandstone and its white and brown contemporaries, formed from the grindings of other rocks subjected to enormous pressure, and lastly the geyserites and sulphur rocks, soft and honeycombed, the result of ceaseless spoutings of steam and hot water from the earth's bowels—all are found in wonderful profusion.

Below the canyon where the river runs more peacefully, all these formations are represented in the huge beds of cobble stones and smaller boulders over which the water plays. The cobble stones were themselves once jagged rocks, detached by wind, water, frost, and sun, from their mountain bases and rolled and ground by river force until all their sharp corners have been worn and polished away.

* * *

A Giant Fire Cracker—Watching the government engineers cutting a road along the side of the canyon for the transportation of supplies to build the dam—60,000 barrels of cement alone will be needed—I observed the explosion of a big charge of dynamite, which burst with a roar echoing up and down the canyon with deafening reverberations. Immediately an oblong granite rock of some 150 tons weight was torn from its base and hurled down into the river a hundred feet below. Shatters of rock flew in all directions and a great splash of water rose like a geyser out of the black depths of the canyon into the sunlight in a majestic water spray. Yet this huge block of granite was but a baby addition to the family of boulders which had been detached by the more giant forces of nature and thrown into the river bed. A few hours before I had crawled directly under this rock in my canyon exploration. Returning I was glad to accept the assistance of one of the road builders in getting across this place, looking down the while into the river boiling below among the rocks.

"If you slip, you can get out a quarter of a mile down stream," remarked one of the dynamiters cheerfully, as I passed my camera over and was inching across this slippery six feet, clinging to the canyon side.

The engineering credit for this great project with its great dam, its enormous spillways, its mountain road building and its miles of canals and huge tunnels bored through the solid rock, is due to Jeremiah Ahern, a government district engineer who, almost cut off from the outside world, has taken up his residence for several years in this wild canyon, once a fastness of the Shoshone Indians.

* * *

National Irrigation.—What does all this great irrigation work of the government throughout the west signify?

CAN CHECK THE PEAR BLIGHT.

Professor Waite, who knows more about pear blight than any other one man in the United States, having made a special study of it for the Department of Agriculture for many years past, assured the writer that he is so confident of his method of treatment, which consists of cutting out the hold-over blight in the fall months, that he purchased a tract of land in the blight infested section of the east and set it all out to pears. If there is any sure check for this disease, the man who plants out an orchard now will make money when it comes to bearing. There is a strong disinclination for planting pears on account of the disease and very many of the old orchards are being abandoned or dying out and in another five years the man who has a bearing orchard of Bartlett pears will have a sure income. Prof. Waite has faith in his methods and it may be wise to follow his advice and example.

* * *

GATHERING STATISTICS.

The statistic blanks which have been prepared by the State Agricultural Society are now ready and in a few days will be in the hands of the supervisors of the different counties. The work of gathering statistics is made mandatory on the different counties, and it is to be hoped that it will be faithfully done, as there is a great need of the facts and figures which it is sought to obtain by this means. Heretofore most of the statistics have been gathered by the assessors and, even where they have done their duty, they have found it difficult to get the desired information, as many of the people believed the figures were desired for taxing purposes and failed to tell the truth. In other cases, the assessors have regarded this work as so much extra labor put upon them for which they received no compensation and have either failed to attend to it or have done the work so badly that it was worthless. Under the new arrangement we shall be able to secure reliable data in regard to the horticultural and agricultural wealth and progress of our State. There is nothing which conveys information so well as accurate figures and under the new law we may hope to receive these from all the counties.

* * *

PARASITE FOR PURPLE SCALE.

Several years ago, during one of Compere's visits to China, he discovered a lot of very badly parasitized purple scale. It was during the time of the Boxer troubles, and he was unable to pursue his investigations very thoroughly, but he secured a quantity of infested twigs and forwarded them to Mr. Craw. The condition of the scales, the long voyage, and the lack of sap in the twigs, rendered the sending useless, except as a proof that the purple scale in China has an effective parasite. A new effort is to be made to obtain this parasite, and an effort that will probably be crowned with success. To make certain of getting the parasite here in good shape, California orange trees infested with the purple scale have been forwarded to China; these will be taken by Compere and placed in a position to become thoroughly parasitized with the little enemy of the scale; as soon as this is done the trees, with their scale and contained parasites, will be carefully packed up and forwarded to San Francisco, where every preparation will be made to receive and breed them for general distribution. That there is an effective parasite for this pest to be found in China there is no doubt, for the writer carefully examined the original package of twigs forwarded by Compere and found on them a large quantity of scales, but of these at least ninety per cent showed evidence of parasitism. While on this subject of parasites, I note that the Scutellista cyanea is doing all, or even more, than was claimed for it and we have reduced another of our scale enemies to complete subjugation. The work of this little insect on the black scale has been almost as remarkable as that of the Vedalia cardinalis on the cottony cushion scale. The new parasite of the codling moth, which Ashmead has announced as Calliephialtes messer, is also sending in good reports and gives promise of good work yet. It is yet too early to assert positively what it will accomplish, and it seems almost too good to believe that we have an effective check for the codling moth, but reports from disinterested sources are so good that we are very hopeful.

* * *

A NEW PLUM.

Frank Femmons, of Ahwahnee, Madera county, has produced a very meritorious new plum. It is a seedling, produced on his place, and has been in bearing for several years, so that its good qualities have been tested. Its special qualities are its size, which is large, color deep purple, and very uniform, it ripens early and colors perfectly before the fruit is perfectly ripe; it is a good shipper and of excellent flavor. Another advantage, in sections where late frosts are liable to come, is that it is a late bloomer. Taken altogether it is one of the best all around plums we have seen and in honor if its originator it has been decided to call it the Femonzi, or Femmon's plum.

* * *

FIGHTING THE PEAR BLIGHT.

In accordance with his early arrangements Prof. M. B. Waite, pathologist in charge of diseases of orchard fruits, with the Department of Agriculture at Washington, arrived last week, and at once commenced his investigations into the condition of the pear orchards in Northern California. Prof. Waite's one remedy is cutting back—and especially cutting back late in the fall—what is termed the hold-over blight.

During the growing season of the tree the blight is spreading through it, the more rapidly as its growth is more vigorous. When the tree becomes dormant for the winter, the spread of the blight is stopped. It is then that the most effective work can be done. By searching out all the blighted parts, and cuting out all of these parts, a good distance below the point shown to be affected, all the germs of the disease can be removed, and there being nothing to give it a start again the next spring, it necessarily stops until it gets a new start from some other source. It is likely that if all pear growers whose trees are affected would faithfully follow out this plan, we should be able to control the blight

BEE KEEPING FOR BEGINNERS

It occurs to me that there are three lines of work which it will pay our Government to undertake on behalf of beekeepers. It was my pleasure recently to pay a visit to Dr. E. S. Phillips of the Department of Agriculture, at Washington, who has charge of the apiarian matters, in the absence of Mr. Benton. Dr. Phillips is a young man, but he has made a very thorough and comprehensive study of all our most important bee problems. I doubt if more wisdom could have been shown than was manifest in his appointment to the department. We talked over the matter which I have already referred to in the Cultivator, of research work in the line of determining those parts of the country best adapted to apicultural pursuits. Dr. Phillips seems just as interested in this matter and quite as enthusiastic in regard to its importance as any one could be. I believe if he can have his way, and a man of his energy is very likely to gain his point, there will be, ere long, valuable investigations in this direction. The second matter, that of importing new bees in hopes of improvement, is certainly very desirable. Mr. Benton, as we know, is already on his way to the Orient, in quest of new and untried races and species of bees. Surely no one in the country is better able from knowledge and previous experience to carry on this work to a splendid consummation than is Mr Benton. Even should we not gain any advantage from such importation as he may make, we still shall gain a most important point. The matter will be settled once for all and we shall no longer waste energy in laboring to secure these importations. Dr. Phillips informs me that there is also an effort being made to secure the stingless bees of Mexico and South America. It is hoped that these bees may be of value. It has even been suggested that possibly they might be crossed with our common bees to our advantage. While I have no faith at all in such a cross, as these bees seem very different from our ordinary bees, yet in the interests of science, I am heartily in favor of the introduction of the Melipona and others into our country. The scientific importance of the matter more than warrants the expense. We may all be justly proud of the grand work that our country has done in the past in the direction of scientific work. The introduction of the bees of the genera Melipona and Trigona will be looked upon with great interest by all scientists and we may well hope that the government may not let this matter end simply in talk.

The third matter has to do with the improvement of our present bees. I have long believed that here was a fruitful source of great benefit and I was specially pleased to find that Dr. Phillips is wide awake in this matter and has already commenced valuable experimentation looking to such improvement. Who shall say that the valuable work wrought by Luther Burbank in his marvelous experiments with our various vegetables and fruits may not be duplicated by Dr. Phillips in his research work with our bees. It has long seemed to me that this was a specially inviting realm for the wise scientist. The honey bee shows a marvelous susceptibility toward improvements. Where else in the whole realm of nature do we find such remarkable variation? Even with natural selection alone, the bee has shown marvelous development. Think of the queen bee laying nearly twice her own weight of eggs each day. Except in the case of the white ant we have nothing comparable to this in all the sphere of animal life. The bee can do more things and do them well than any other animal. This implies a wonderfully varied anatomy and he who studies the bee finds just this. This should not be the work of a day, month, or even year, but should extend over a long series of years. We all know what signal improvements have been made in breeding our horses, cattle, sheep, dogs, etc. There is no reason to doubt but that the same assiduity which has wrought so well in these lines may not accomplish quite as much if not more in similar work with our bees. Surely we will all watch these researches of Dr. Phillips with exceeding interest, believing that with his excellent scientific training, his full knowledge of the requisites for success, we may reasonably expect splendid fruits. I am sure that Dr. Phillips will have the sympathy and appreciation of not only every beekeeper but also of every scientist of the country.

* * *

A GOODLY EXHIBIT.

One of the conspicuous objects on the magnificent lawn fronting the agricultural grounds of Washington is a beautiful apiary. Every visitor who goes up from Pennsylvania avenue to visit the several departments where so much is to be learned concerning every phase of agricultural development, will see off to his left towards the Smithsonian Building and the National Museum a goodly array of bee hives, each populous with its thousands of ever busy bees. This recognition of the importance of the apiary in our social affairs, is certainly most gratifying. Bees not only conserve a valuable food product which would otherwise go to waste, but they are also of inestimable value in the great and necessary work of cross pollination of our various fruits and vegetables. The government, by locating an apiary so prominently on the ground devoted to agricultural research, shows to the world a recognition of the value of the honey bee, which I believe is without precedent anywhere else in the world. Surely the world moves and we will all be grateful.

* * *

A PROMISING ENTERPRISE.

I was very glad to learn that Dr. L. O. Howard is now in Europe in quest of enemies of the Gypsy moth. As we all know, this moth was introduced into this country from Europe nearly forty years ago. It is not only a vegetable feeder in common with all moths and butterflies, but, unlike most species, it is an indiscriminate feeder, like the cottony cushion scale, caring little on what variety of plant it feeds. Thus it became in twenty years from the time of its introduction a most threatening pest. Over a million dollars have already been spent in the attempt to eradicate it. I doubt if it will ever be possible to eradicate any insect after it becomes once well established, especially such a promiscuous feeder as this. I believe that the Colorado potato beetle was exterminated in Germany, but this was just as it had commenced its work and was the result of the very thorough work so characteristic of Germans. After California's wondrous success with the Vedalia, it would seem that the first effort of Massachusetts would have been to import the enemies which hold the Gypsy moth down in its native habitat. At last, this course has been decided upon. The last legislature of Massachusetts appropriated $30,000 to be expended in this work. I hope and believe that this will be more effective than the million already expended. May not the government learn from Massachusetts? She appropriated the paltry sum of $2500 for such work during the last Congress.

* * *

THE SECRETARY OF AGRICULTURE.

I promised in my last to say a word more regarding the unkind reports concerning the Agricultural Department. I doubt if a more unselfish, earnest body of workers exists, than is now to be found in the various bureaus of our Department of Agriculture. I myself, still feel grateful to Dr. Moore for his splendid discovery and to Dr. Salmon for his long and valuable service, and I doubt if they have done anything that they believed wrong or disloyal to the government or the department. There may be a very few cases of venial or dishonest practice. I find that nearly all the workers here—grand men—who are entirely above selffish acts or dishonest practice are very slow to believe these rumors. We may all rest assured that Secretary Wilson will probe matters to the very bottom, and that justice will be fully done. In the meantime let us defer judgment.

GREEN MANURING.

There will be more planting of field peas for green manuring this year than ever before. There will also be used some lupins and vetches, but less of these, owing to the inability to obtain seed.

Some are already getting the ground into condition, but more are waiting for next month, which is generally considered the best time for planting. As to the peas, there are two varieties usually preferred, the Canadian White and the Prussian Blue, sometimes call the blue field pea. As near as we can learn the Canadian Field Marrowfat is nothing more nor less than the blue field pea. Of the two varieties there seems to be but slight preference, though some orchardists say that if they could secure the Canadian-grown white pea they would prefer it. It is claimed the Canadian grown seed furnishes a heavier growth than the California grown.

TOOLS

The name Keen Kutter eliminates *all* uncertainty in tool buying. As this brand covers a complete line of tools, all you need remember in buying a tool of any kind is the one name Keen Kutter. Keen Kutter Tools are without reserve or qualification the best tools that money, brains and skill can produce. No matter how much you pay, no matter who you may have thought to be the best maker of a particular kind of tool, you cannot get any tool, anywhere, better than those sold under the name of Keen Kutter. If your dealer doesn't keep Keen Kutter tools write us and learn where to get them.

KEEN KUTTER

Tools received the Grand Prize at the St. Louis Exposition—the only such award ever given a complete line of tools.

Some kinds of Keen Kutter Tools
Chisels, Knives of all kinds, Hair Clippers, Scissors, Shears, Adzes, Axes, Brush Hooks, Choppers, Corn Knives, Cleavers, Hay Knives, Scythes, Saws, Horse Shears, Tool Cabinets, Etc.

J. A. W. GATES, 216-218 West Second St. Los Angeles, Cal.

HYBRIDIZING THE LENOIR AS A RESISTANT ROOT.

At the recent meeting of the California Viticultural Club, Newton B. Pierce, pathologist in charge of the Plant Improvement Gardens at Santa Ana, furnished a paper on the California vine disease, from which we quote the following:

Few Vitis vinifera varieties of grapes are able to withstand the epidemic development of the California vine disease. The hardiest of the European types usually die of the disease, sooner or later, when situated in the midst of an infected district. The exeeptions to these statements are few, and in most cases are more apparent than real—i. e., a vine or variety showing much hardiness in one situation may clearly show its susceptibility under different circumstances.

Among the whole list of cultivated grape varieties thus far studied when subjected to the influence of this disease in its epidemic form, the Lenoir grape is most resistant. It is so hardy in the face of the malady that it forms, in conjunction with its blood relatives, a class by itself. The work of the United States Department of Agriculture has demonstrated this beyond a reasonable doubt. Vineyards eight, sixteen and twenty-three years old of the Lenoir grape are now bearing eight tons of fruit to the acre in the midst of the earliest infected district in the State, and where the surrounding vineyards, tens of thousands of acres in extent, have long since perished.

Hundreds of acres of grafting experiments with Lenoir roots have been instituted, largely through the aid of growers, and these experiments have shown that the Lenoir root will materially prolong the life of a tender top variety, though not making such top immune. The reason for the lack of perfect immunity in the top is evident from the fact that the California vine disease affects all parts of a vine, not simply the root system, as with phylloxera. In grafting a tender top on a Lenoir root the vineyardist produces, approximately, a plant representing in resistance the sum of the percentage of hardiness of the root and top varieties divided by two—or practically one-half the total percentage of resistance of the two varieties united in the new plant as determined when they are growing on their own roots. It is, hence, apparent that the top to be used in all grafting work looking to the extending of the life of the vine in the presence of this disease should be of that variety having the highest degree of resistance to the disease, and which possesses the desired qualities of fruit and yield.

In view of the scarcity of such hardy and otherwise satisfactory types, the writer has been hybridizing—and will continue to hybridize—the Lenoir with all classes of wine, table and other varieties and species of grapes. The object of this work is to develop, by breeding, an entirely new family of grape varieties, each of which will inherit hardiness through direct blood relationship with the Lenoir. Hundreds of these hybrids are now growing at the Plant Improvement Gardens of the Department, at Santa Ana, Cal., and this line of work is being expanded as rapidly as time, means and the maturing of seedling plants and grafts will permit.

THE 1903 RAISIN STATEMENT.

"The long delayed statement of the 1903 raisin crop is now in the hands of the members of the California Raisin Growers' Association," says the Fresno Republican. "As will be recalled, an advance of 3 cents was made to growers in the early stages of the marketing season, but the market failed, the goods did not move, and the result was that some of the growers received less than 3 cents and others obtained nothing at all. The association in order to keep the advances up borrowed half a million dollars on the crop as security and growers who did not receive their advance borrowed more from the banks, giving their personal notes. The statement issued deals entirely with the grower in his relation to the assoeiation and not to the bank.

The net price per pound brought by the crop is computed on each grade of raisins delivered by each grower, according to the pack-out records. Whether he was underpaid or overpaid appears on the statement. Those who were overpaid are asked to return to the association the amount of the excess advance, while those who did not receive the amount they are entitled to have the satisfaction of knowing it's coming. Final settlement, however, depends upon the termination of litigation now in the courts. The statement is prepared upon the assumption that the association will be successful in the two suits recently tried, that of Chaddock & Co., and the Co-operatives. In the latter case Judge Church, while formally withholding judgment to admit the filing of briefs, indicated in positive terms what his decision would be.

It is difficult to state what the year's price per pound for an average crop was, for the reason that crops differ so greatly in the proportion of high grade goods, but as fair an estimation as can be made is between 2.4 and 2.5 cents.

Quite a number of the growers who have received their statements called at the office and returned the over advance. It is not expected that it will be necessary to resort to many suits, but no doubt some actions to recover will have to be brought. The time is now short, as many of the claims outlaw in September and all of them not later than October."

LAYERING PLANTS.

Carefully layer plants of raspberry, blackberry, currant, gooseberry, grapes or strawberry each year and thus have new ones without buying. By layering only from strong, healthy plants a high standard will be maintained. After plants are done bearing, pick out the finest lower branches from bushes that have produced well, press to ground and throw over a shovelful of dirt a few inches from end of plant. When plant is rooted, loosen from parent stem and it will be ready to set out in the spring.—Sueeessful Farminf.

BEES FOR SALE

I wish to sell my apiary consisting of 43 colonies of bees in A 1 condition. 100 L. hives, 120 supers, 85 shipping cases, tanks extractor, etc. Will sell cheap for cash.

STUDEBAKER FRUIT WAGON

STUDEBAKER WAGONS

ARE STANDARD THE WORLD OVER

When quality is the consideration there is only ***one selection.*** Studebaker wagons stand upon a reputation established by quality. They are not only the best, but they are sold at a price which is within the reach of every purchaser. Studebaker wagons are made by ***experienced artisans.*** They are built upon the most improved lines with the latest and best machinery. Everything is ***first-class*** from tongue to tail board. You will make no mistake by purchasing a ***Studebaker,*** but you will likely make a mistake if you buy any other kind of a buggy or wagon. We have a ***complete line*** and would be glad to send you our catalogue to show you what we carry in stock. A ***Studebaker*** will always give you ***entire satisfaction*** and meet every demand made upon it. We are the local agents.

CITRUS FRUITS

By C. A. Day. Pasadena

TREATMENT OF BLACK SCALE.

There are different methods of treatment for the control and destruction of black scale and each of these different methods have their advocates.

It is not for the citrus department of the Cultivator to advocate any particular method, but to state the facts as we know them and leave each individual grower to choose his method of treatment. The writer favors the method that will give the best results, regardless of expense, and the grounds for this belief are based on the fact that it pays to protect the citrus tree from the insect enemies that prey upon it. Whatever method is adopted the orchardist should see to it that it is thorough and effective. To treat an orchard by any given method and leave a good stock of scale as a continual draft on the resources of the tree is, in my belief, a mistake and will result in financial loss to the grower. In a former article I made a statement of how the black scale injures the citrus tree and its fruit, and to give force to the claim that it pays to thoroughly clean the tree from black scale I again repeat the substance of that statement. The injury is from loss of the elaborated sap of the tree diverted to the support of the scale, the heavy coating of smut which covers the leaves interferes with the trees' function of digestion. The smut which covers the fruit prevents the proper coloring of the fruit, the draft on the tree often reduces the set of fruit and lowers its quality. Smut on the fruit makes washing necessary and adds to the expense of production and produces loss from additional decay, due to additional handling of the fruit and possible increase of moisture of the packed fruit. In other words the scale reduces the quantity of fruit, lowers its quality, increases the chance of decay, and adds the expense of washing. Money expended for ineffective treatment is money thrown away. Whether we spray or fumigate, the object is to effectually destroy the scale and clean the tree.

* * *

SPRAYING.

The old rosin wash is the most effective spray for black scale and is to be advised for use in cleaning up citrus nursery stock, but in orchard work it sometimes spots the fruit and is expensive. Distillate emulsion comes next for effectiveness, but frequently spots the fruit and is but little used. Distillate mechanical mixture comes next in the list and has been strongly recommended because of its cheapness and because it can be used for both the red spider and black scale at the same time. I have seen a great deal of poor work done with this spray and I have noted some good work. I do not mean by good work that it was equal to the best work by fumigation, but that it reduced the scale to a point where they would do but little injury to the tree and the fruit did not require washing. Spraying does not destroy all the scale and with fair work leaves enough scale to mature that will next year fully retsock the tree.

Poor work is in part due to the following causes: Scale not being in condition to treat; to weak mixture and a hurried, careless application.

* * *

Condition of Scale.—All the young scale should be hatched and out from under the shell of the old scale and the earlier hatch of scale should not be too far advanced towards maturity. The right time for the treatment of the scale of an orchard does not last for any great length of time and where a single sprayer is run for three months or more a portion of the work is done when a part of the scale is out of condition and of course are not destroyed. For good work there should be a pretty even hatch of scale. On young, vigorous growing trees we very frequently have an uneven hatch, and it is impossible to treat the scale when they are all in condition to have good work done.

The orchardist should be well enough posted to know when the work should be done, otherwise he may be deceived by an unscrupulous sprayer. Some have advised the growers to cooperate and buy a machine and do their own spraying. This is not always a success. First, because too large an acreage is taken in; second, incompetent help are employed to run the sprayer.

* * *

Location of the Scale.—When the scale first hatch they not only locate on the wood, but in large numbers on the leaves, usually on each side of the rib of the leaf and on the upper side of the leaf. The young scale have the power of locomotion until well grown and eventually move from the leaf to the young wood. On an orange tree of some age the scale permanently locates on the new wood on the outside of the tree and prefer the under side of the twig or limb. A greater part of the scale are usually found when fully grown on the under side of the limb. In spraying a tree with a close, thick top and heavy foliage, the spray should be brought to bear with full force on the under side of every limb and twig. There should be no hurrying and plenty of material should be used. Every inch of leaves and wood should be thoroughly soaked. With a spray of sufficient force the oil will be driven against the surface of leaf and wood and will stick fast. The amount of oil accumulating on the surface of the leaves and wood will depend upon the time of duration in spraying. Poor results are in many instances probably due to hurried, careless work.

* * *

STRENGTH OF MIXTURE.

On orange trees from 2 to 2½ per cent of distillate is used, depending on condition of tree. The tree should not be sprayed when suffering for water. Irrigation should precede spraying by a few days in order that the leaf cells shall be filled full of water and be better able to resist the effects of the distillate. For killing of the scale 2½ per cent of distillate will do the best work. Quite a number of our growers use 2¼ per cent on orange trees.

Lemon trees will stand a stronger mixture than the orange. If in good condition, at least three per cent of distillate. Turpentine is used by some of our sprayers, one quart to every hundred gallons of distillate and water mixture. Cool weather is preferable to hot. Cloudy days, which are so rare here in California, are ideal for spraying.

INJURY TO TREE.

With mechanical mixture there is but little chance of injury to the fruit. If the mixture is too strong or the tree out of condition, its effect upon the tree is to drop some of the leaves, usually the older leaves, and kill the inner wood of the tree. In both cases the enfeebled condition of the older leaves and the wood on the inside of the tree, the result of age, makes them less able to resist the effects of the distilliate than the younger and more vigorous wood and foliage.

* * *

FUMIGATION.

In fumigating for black scale we must have all the young scale out from under the shell of the old scale. With proper fumigation scale well advanced to maturity can be destroyed. The conditions of the contract with fumigator should be, inspection of work by the horticultural commission, the grower to pay for the cyanide used and the labor item of so much per tree be made a separate charge.

Equal proportions of cyanide and acid should be used with the proportion of water, four to one, and the tents should be left on the trees one hour.

With this proportion of water there should be an increased amount of cyanide used to secure the proper density of gas, as the increased amount of water causes a slower generation of the gas. The old way of using a smaller amount of water caused a quick generation of the gas and with a heavy dose, burned the tender foliage of the tree. Fumigation of trees when wet with dew will be very likely to injure foliage and fruit, as the water absorbs a large quantity of gas and when so charged will injure the foliage and fruit with which it comes in contact. In experimental work by members of the Los Angeles County Horticultural Commission a double dose has been used, with the proportions of water, four to one, without injury to fruit or tree. This is not to say that we recommend a double dose for ordinary work, as the condition of the tree has a great deal to do with the success of such an experiment. For black scale alone, when not too far advanced, an extreme dose is not required to kill the scale. Success with fumigation depends upon the ability of the fumigator to rightly estimate the amount of material per tree, and careful, conscientious weighing out of the material, according to the schedule, and the giving of the right proportion of water. At the present time in connection with the scutelista which has destroyed the late scale, fumigation should make perfectly clean work of the black scale that will last for two years. Fumigation has no effect on the red spider, but is beneficial in destroying the scattering specimens of red, yellow and greedy scale that have gained a foothold in some of our orchards. This latter fact alone makes it advisable to at least occasionally fumigate the citrus orchard, in order to exterminate these species of scale.

* * *

COST OF FUMIGATION.

On an ordinary sized tree the cost of fumigation is double that of spraying. In order to compete with the cheaper method of spraying some of our fumigators are inclined to cut down the quantity of material used and the time of covering the trees. This has resulted in poor and unsatisfactory work. If fumigation is to be done at all it should be well done so as to last at least two years. As fumigation will not kill the red spider, the latter, if present in the orchard, will have to be given a separate treatment of suiphur or distillate. A single spraying of distillate will not always catch the black scale and spider in the right stage for effective treatment for both insects and in this case two treatments will be necessary.

LEAF MOLD.

Nothing that can be added to garden soils contains so much that is desirable as does leaf mold. Not only does it contain the most valuable plant foods, but it will do more to ameliorate the conditions of soils either too heavy or too sandy, than all else that could be added and is never injurious to any soil, being in every case exceedingly beneficial.

In the cities leaf mold costs at least five dollars per load, and a poor quality at that. Every garden fairly cries for it, yet no one may have all he wishes except the farmer. There is no reason why the farmer with such material, and plenty of other natural fertilizers at command, may not have better success in the garden than those in cities or towns. Leaf mold does more to relieve the gardener from excessive irrigation and cultivation than any other factor; during the summer months, when it is light in weight, every farmer should put a few loads into his garden.

* * *

THE WINDMILL PALM.

As we go north in our very lengthy State, the palms gradually disappear and in some parts none can be found. We fear that the reason for this lies in the general belief that palms can be grown only in the most favored parts of California. The truth is that we have several palms that will not only grow in the coldest parts of this State, but will stand snow and freezing. The Wine or Honey palm (Jubea spectabilis) is the most southerly in range of all American palms, and is, therefore, very hardy.

The dwarf fan palm (Chamaerops humilis) of Europe, is another for snow-clad lands and the palmetto of the Southern States is equally hardy.

One of the most satisfactory palms for all sections of the Pacific Coast is the one we illustrate. It grows in the south of England and Ireland, where they often have freezing weather, with plenty of sleet and snow. Even in colder regions, where the leaves have been frozen off each winter, this palm has attained considerable size and age. All throughout our State it seems to be perfectly at home and will stand more ill usage from man, animals and the elements than any other. Those in the far north or in mountain regions subject to severe winter weather, will find any of the four plants mentioned worthy of a trial, with the assurance that they will stand any California climate.

TRANSPLANTING LARGE TREES.

It sometimes becomes necessary to remove large trees that have been planted for many years, and which are too valuable to destroy while it is possible to utilize them elsewhere. In such cases they can be moved with safety if the work is carefuliy undertaken.

The autumn is the best season for transplanting (about September 1) and work should be commenced by digging a trench 3 feet to 4 feet from the stem of the tree to be moved, going down deep enough to ensure all the main roots being cut off. Whether the ball should be made round or square is entirely a matter of convenience in handling, but a round ball is usually much more convenient, unless transplanting box is used, besides being easier to cut out. When the depth of the main roots has been reached, a small pick with a short handle should be used to cut underneath the ball, cutting through all tap roots, and keeping the lower part of the ball as level and as firm as possible.

If the tree is found to have a good many fibrous roots and comparatively few main roots, and the soil is "heavy," it may be moved at once, for which purpose a few rollers, 3 inches or 4 inches in diameter, and some stout planks and ropes are necessary. A slope should be dug in the direction

The Windmill Palm.

the tree is to go, and planks laid down it, care being taken to get a couple of planks right under the ball, and on these latter two rollers should be put. On the rollers place pieces of board sufficiently wide to take the greater part of the ball, and projecting a little way beyond it. A mat or piece of canvas should be tied around the ball and some short pieces of board over it to take the rope, the ball "canted" over, and the tree pulled out. If the tree is found to have few fibres and a great many large roots, or the soil of a sandy nature, it will be practically impossible to move it with any soil attached unless boxed. In such a case it may be filled in again and left for a year, or even two, during which time, through the cutting of the main roots, many small fibrous roots will be formed, and it can be removed with greater safety.

When planting a tree that has been moved, the ball should be carefully measured, and a hole dug large enough to take it, while allowing 18 inches to spare all round. One side should be cut away to allow the tree to be run in. When in position fill in the soil to about two-thirds, or a little more, of the top, and make it very firm. The remainder of the hole should be filled with water, and left for two or three days to settle; then it should be filled with good soil, and the tree made secure by guy ropes or wires if top heavy or very tall.

THINNING TREES.

Of course, there should seldom occur the necessity for thinning out trees. The future growth of trees should be considered when rows or groups are planted, and each individual tree be given space for future development. On the other hand, it must be admitted there are cases where quick results are desirable. For instance, an old man—or a middle-aged one—does not always feel so responsible for the future as to plant trees in a manner to give the desired results only after his death, perhaps he would say, "Let the future generation thin them out."

Whatever the reason for close-planting originally cases will continually arise where trees are found injuring one another, or nearly so, and decisive steps must be taken to correct the trouble. We recall the sight of a really magnificent avenue of trees which are being gradually made worthless. They long since grew into each other, and by excluding light and air from the lower branches, they have become tall and spindling, the side branches dying and ravaging the health of the trees generally. There is no hope for them now, for by cutting down every alternate tree, only old wrecks are left that would never regain symmetry. These trees were set at a fairly good distance apart, but should have been thinned out long before the question was raised.

For general street and avenue planting, 25 feet is the distance usually allowed, with trifling variations depending on the character of the tree. Occasionally 30 feet is allowed, and some rapid growing tree, like the poplar or silver maple, is temporarily planted alternately with the permanent ones, making trees every 15 feet. In the course of time, the commoner temporary trees are removed.

Then there are occasionally uncalled for thinnings on large places. Beautiful strips of natural woodland will be denuded of all underbrush and small trees and large trees taken out at regular intervals. The beautiful natives are rooted out because they are not shapely and all wild flowers are leveled. Where nature is, let her reign, unless cause for a change is very evident. If a little thinning be necessary, let it be the best and most permanent that remain; and the more natural appearing, the more peace-giving and charming generally.

HAVE YOUR WAY.

It is best for us to be slow to criticise those whose taste in garden display does not agree with us, remembering that "there is no disputing about taste," and that each has a perfect right to his own, and those who disfigure their lawns in any way probably take as much pleasure in the disfigurement as do others take displeasure. One best enjoys a twilight rest in a rustic seat, another can find rest just as refreshing upon a bench made of an old drygoods box. If we all wanted the same thing there would be more quarrelsomeness in the world than there is now.

MELON PEACH.

One of the Cultivator subscribers at Mecca sends us the following account of a new variety of cucumber which he says has been successfully grown under desert conditions:

"Did you ever eat a melon peach? No; what is it? It is a fruit growing on a vine and much resembles a mock orange. Out of curiosity some seed was purchased from a Philadelphia seed man and planted in the garden. As a curiosity it was satisfying, but for culinary uses it did not seem available. It is a fact that cucumbers can not be successfully grown everywhere on the Colorado desert. One man may raise them successfully, while all his neighbors make a failure. Cutting one open it looked very much like a cucumber, and a taste did not belie the eye; forthwith several were sliced and an experiment made, result was that the melon peach filled all requirements for a cucumber salad. Why it has been named melon peach is hard to say, as it neither tastes nor looks like a peach. The fruit thrives well in the heat and salty soil. It is very prolific and sets fruit all through the summer. It is about the size of a Mediterranean orange, and can be eaten either yellow or green. From appearances it is a hybrid cucumber fertilized with canteloupe pollen. The canteloupe blood in the melon peach makes it at home in the Coachella valley.

But the melon peach is not the only curcubit that can be substituted for the cucumber. Recently a gentleman related to me that he ate dinner at the home of a rancher near Mecca. After the viands had been disposed of, the host asked him how he liked the cucumbers. He declared he had never eaten finer. To his astonishment he was told that he had eaten canteloupe salad. The canteloupes should be green and before they show much netting. Those who sigh for the cooling cucumber and have it not, should make a trial of either the melon peach or canteloupe for salads, and it will eliminate all yearning for that vegetable. The season for canteloupes is short, but the melon peach fills the interim between late and early fruit.

It is not those who are always telling about their troubles who suffer most.

General Agricultural Notes

THE 1905 GRAIN CROP.

Reports from all parts of the country, especially through the great grain producing section of the Mississippi valley show that the cereal production of the United States this year will about equal that of the record year of 1902. On the basis of the government report, the production of all grains will be about 4,344,000,000 or 6,000,000 less than that official yields for 1902.

From present reports on the corn crop, it will be a record breaker. The government figures place it at 2,595,000,000 bushels, of which 1,684,000,000 bushels are in the surplus States, showing an increase in the latter sections of 246,000,000 bushels over last year. This latter estimate may be cut down, owing to hot and dry conditions in parts of Iowa. Nebraska, Kansas and northeastern Missouri.

Reports from winter wheat sections show yields averaging two bushels more than last year. In parts of Michigan, forty bushels to the acre have been made and the average for that State will go about nineteen bushels. Nebraska has the banner yield of the country, averaging 20.4 bushels. This gives that State 48,000,000 bushels of wheat. In Kansas the yield is only a fraction under fourteen bushels. Oklahoma has the lightest yield per acre in any year, being 8.2 bushels.

A good crop of oats has been assured, the yield being about 900,000,000 bushels.

Barley is about an average crop. The crop of flax in the northwest will be large, while the outlook for buckwheat is above that of last year.

THE AGRICULTURAL PRESS.

J. Lewis Draper, secretary of the National Agricultural Press League in the August 16th issue of the Printer's Ink, says:

"There were in the United States, at the time of the last decennial census, 5,739,657 farms, representing a total fixed investment of $20,514,001,838, and directly supporting close to half of the productive workers of the nation.

Of course it is trite to say that agriculture is the basis of our prosperity; nevertheless, it seems difficult for the average man of affairs to realize what a large percentage of the money he handles comes from the rural population. Agricultural and live stock products aggregate in value approximately four billion dollars.

To reach these six billion homes and that four billion dollars ought to be a matter of concern to every manufacturer of a legitimate commodity of life.

Fortunately for the manufacturer and the merchant there is a means of easy and convenient access to these minds and pures.

Rowell's American Newspaper directory for 1905 lists, under the headings of agricultural, live stock and dairy publications, 419 papers, with an aggregate circulation of probably over 6,000,000 copies."

In the California list the Cultivator is the only paper given credit for a circulation exceeding 10,000 copies. That the Cultivator has the circulation credited to it, we are prepared to prove to any advertiser at any time.

TO KILL MORNING GLORY.

It will be recalled that the Cultivator has given many remedies for killing morning glory, the best of which, that of the use of salt solution, given some months ago. We now note another remedy, recommended by Major Charles P. Braslau, of the Braslau Seed Co., Santa Clara Valley.

The remedy as given in the Mercury looks good, can not be very expensive, and we believe will be very effective. It is as follows:

"There is a very simple remedy, which every farmer, every orchardist, every holder of land, whether in small holdings of a few acres, or in large ranches, ought to know and to use. It is this: Where you have a patch of morning glories, roll or flatten the spot out as flat as possible with either a roller or a board; then lay tar paper, such as is used in building, over the whole patch, pressing it down flat and close, and put some earth on top of it all around the edges, to exclude the air and the light.

"Every plant needs four elements for its growth, as a rule, earth, water, air and light. If you shut out the air and the light from a plant it will die, and so if you keep out the air and light from the morning glories, leaving the tar paper on for six weeks, at the end of that time your plants will be dead and the roots will be dead also."

FRUIT CONDITIONS IN EUROPE.

From special consular reports of fruit conditions in Europe, the following will be found of interest:

The Spanish almond crop in the district of Alicante is reported poor. While the crop will be of fair size, the kernels are very small and poor. This district shipped to the U. S. last year 409 tons of almonds, valued at $162,244.

The summer lemon crop at Messina, Sicily, is about one-fourth less than last year, and the quality better. The almond crop promises to be of good quality, with prices quoted for October delivery at $28 per 224 lbs.

The report from Castallammau di Stabia, Italy, states that the lemon crop is almost a total failure. The output will be under 10,000 boxes and prices expected to be $3.00 per box f. o. b. The walnut crop in this district will be about one and a half times that of last year.

The lemon crop in the Palermo, Italy, district, is good, while the output will not be as large as last year by a third. Prices are high.

According to a report prepared by the Budapest firm of Albert Marko, the outlook for the new crop of prunes in Bosnia and Servia is unfavorable, and only one-half of the amount of last year's crop is expected. There will be perhaps 1500 to 2000 carloads (22,046 lbs. each) in Bosnia, and about 2500 carloads in Servia, for sale in case the crop suffers no further damage. While last year the fruit was small, this year it will be large and of better quality. Only weak middle-crops are expected in Hungary and Austria (Bohemia and Moravia).

Advance sales for delivery in October are already being made as follows. Bosnian—110-120, 95-100 and 80-85 grades in equal quantities at crowns 30.75 (say $7.66 per 220.46 lbs., net cash.

Servian—110-120, 95-100 and 80-85 grades in equal quantities at crowns 27.50 to 28 ($5.58 to $5.68 per 220.46 lbs., net cash.

MORE COMPETENT MEN.

While talking with the manager of one of Southern California's largest orange packing houses recently, we asked him as to the extension of the business of the concern and why other houses were not built, and more extended business conducted under the same management. He replied that the reason is simply from the fact that the right kind of men are not to be secured to handle the extra business. We have asked orchardists wherein lies the greatest difficulty in orchard care and fruit gathering, and almost invariably the reply was "lack of competent help." This was commented upon by G. Harold Powell, of the U. S. Department of Agriculture, when here last season investigating causes of orange decay. He ascribed the greatest loss of orange decay to carelessness of the picker in the use of his clippers in picking, and so it follows all the way along the line from the most ordinary routine work to the general management at the head of the business; incompetent or more often, careless, help. Were it not for this, it goes without saying that California would today be receiving far more than she does for her products, especially those of the citrus and deciduous orchards. Always room at the top, is old and trite enough to be relegated to oblivion, but at the same time it applies to the handling of fruit with such force that it should contain much of encouragement and be a stimulus to our young men.

Value of Crop Statistics.—It has leaked out that the opponents of Secretary Wilson are making an effort to have a bill introduced in Congress this winter to do away with the collection and tabulation of crop statistics. Stock gamblers are at the bottom of the movement and they are basing their campaign on the scandals which have recently arisen in connection with the official crop reports of the Bureau of Statistics of the Department of Agriculture. It must be admitted that mistakes have been made in this, as in many other government reports, but, on the whole, the system is not to blame. It is the incompetence of the agent whose duty it is to honestly collect and correctly tabulate the statistics relating to the crops of the country. Whatever defects exist in the system can be corrected, but it is only through this means that the country can obtain information of the value of its agricultural productions.

"The entire tendency of the age," says the Iowa Homestead, "is toward the collection of facts and statistics respecting all forms of industry. The United States is not alone in this respect. All civilized countries have bureaus or departments of statistics, and their results are more or less promptly placed at the disposal of the whole world. The data thus gathered constitutes a body of approximately correct and reliable information, available for all through newspapers, magazines, almanacs, books and pamphlets. That this information is, on the whole, exceedingly valuable, there can be no doubt. It may be true that, in isolated cases, it is polluted by grafters or misused by speculators; but its collection and distribution are a part of the world's progress which no country can afford to ignore or neglect."

The fact that crop gamblers are the initiates of the movement to stop the collection and publication of crop statistics is the best possible reason why the system should be maintained. It serves as a bureau of information to the public, regulates prices and acts as a check upon all false reports which interested speculators may be disposed to put in circulation. The Homestead very wisely and, we believe, truly says:

"If the government ceased to collect crop statistics, the markets would be much more at the mercy of the speculators than now; for both the "bulls" and the "bears" would have every inducement to fabricate stories of excessive acreage and favorable crop conditions on the one side and of reduced acreage and crop shortages on the other Such reports are now short lived, because government reports already issued or soon to come protect both the producer and the general public from imposition.

With statistical information constantly being collected by the government, the farmer has at his hand at all times reliable information as to what is being done in his own country and throughout the world in supplying the world's demands. Certainly takes the place of uncertainty and light supersedes darkness. If the reports are tampered with, he has it in his power to correct the evil, whereas, if he depended on private and interested sources of information, he could only complain. Thorough information minimizes the range of price fluctuations and insures the farmer a fairer share of the fruits of his toil and investment. Leave it to the speculators to collect and publish all crop statistics, and fluctuations in prices would be sharper, the speculators' control of the market more complete, and the producer's gains smaller."

It is to be hoped that Congress will turn a deaf ear to the dishonest proposition of the speculators to cease the work of the bureau of crop statistics, but instead, empower the Secretary of Agriculture to widen the range of his investigation, to the end that only the most reliable and best informed agents may be secured to bring this branch of the agricultural department to the highest standard of perfection.

* * *

Danger In Fires.—The season is at hand when the closest attention must be given to fires set by campers and hunters. Last year damage from these sources ran into thousands of dollars in all parts of California. Careless campers leaving fires in the morning destroyed one of the most beautiful canyons around Los Angeles, while in San Diego county hunters destroyed great sections of feeding lands by burning off the dried grass, thus depriving stockmen of range which they needed—besides imperiling the life of stock.

Up in the northern part of the State devastating fires were set by hunters, whose criminal carelessness burned over many hundreds of acres of valuable timber land.

When a camp of hunters is made along a road which borders on dried grass, or timber, the farmer should visit the camp daily to see that no fires are set. If he does not do this, he may lose his grass lands or even his buildings. Experience has shown us that but one rule can be followed in this matter, and that is the rule of everlasting vigilance. See to it that campers put out their fires when they leave a place and if they fail to do so, put them out. So many disastrous fires have occurred from this cause that farmers and stockmen can not exercise too much caution.

We were told by a rancher in Kings county, last week, that his loss from campers' fires has run many thousands of dollars in the past ten years. He said he was powerless to put a stop to camping on his lands because he had no time to follow up the men who come onto his lands and set out the fires which destroyed his property. How he would have saved had he put a man on a horse, provided him with means to extinguish fire and kept him continually riding his lands to see that all fires set were put out. It might have cost him a hundred dollars or so each season to pay the services of a competent man, but he would have saved the thousands which he says he has lost.

We speak of this matter, at this time, because we are on the threshold of the season when danger comes by reason of the carelessness of those who seek pleasure without a thought for the injury they may entail on innocent people.

* * *

A Chance for Federal Pruning.—One of the most serious menaces to the growth and development of California, is the system which permits a few men to tie up and own vast unimproved tracts of land. Under Spanish grants, misappropriated homestead lands, and other questionable methods, half a dozen men are said to have half the State. If they were utilizing it the system would not be so bad, but they are not. These lands which today are unoccupied could support thousands of people. In fact the producing capacity of the State would be nearly doubled if the land were divided into small holdings and settled by active farmers and stockmen. There is one firm of cattlemen residing in San Francisco which is said to own a continuous body of land on which they range their cattle all the way from the Golden Gate to the Bay of San Diego. There are other firms of stockmen who own lands in smaller quantities, but their tens and hundreds of thousands of acres which they do not occupy are kept from those who would settle them and double the wealth of the State. According to an article in Everybody's Magazine, Henry Miller of this State, who came to this country a poor German boy, in 1850, has gathered in township after township, until now, as shown by the testimony in a United States court, his holdings aggregate 22,717½ square miles, or 14,539,200 acres. What those figures mean can be better understood by reflecting that they cover an area three times as large as New Jersey—as large as the combined areas of New Hampshire, Massachusetts, Connecticut and Delaware. Miller appears to have been the most successful of all those who have used the machinery provided by the land laws for acquiring land and barring out the actual settlers for whose benefit, in theory, those laws were enacted..

The same authority from which we quote the above figures, gives further examples of the stupendous graft in the lands of California. Some of these run into hundreds of thousands of acres and include lands which belong to the United States government, which have been literally stolen and fenced in. The government should set a strenuous example to these men by instituting an investigation into the methods employed by them in acquiring these lands.

It is a crime to permit them to go on fencing territory which is not theirs and keeping from actual settlement some of the very best and most productive lands in California. The sooner the Federal authorities purge the country of its land sharks the better it will be for the State.

* * *

Peace Declared.—The Russia-Japanese war is at an end. The world will herald the announcement with acclaims of joy. Peace once more prevails and the world will be spared the horror of the further prosecution of the most devastating carnage of the new century.

While, in a commercial way, this nation has profited by the output of its productions to feed the armies and navies of the contending powers, in a humane sense, in the broad sense of desiring peace and brotherly love to prevail all around the world, the United States rejoices that the end of bloodshed is come.

From a national point of view, the United States can take credit for the culmination of the war. No other President, no Emperor, no King, had the moral courage to throw his personal and individual weight into the vortex of war and demand, in the name of humanity, its cessation. It was left for President Roosevelt alone to cast the die. He took the chance of success or failure in his hands. He has triumphed. The magnificent personality of our American President, fearless of results in the presence of such momentous possibilities, backed by the voice of the whole people and the power of God Almighty, in his demands that right shall come out of wrong and war shall cease, has won the victory. The United States is once more the arbiter of nations, a world power of surpassing greatness and undimmed splendor.

* * *

Calling China Down.—The United States has sent China notice that the boycott upon American goods must be called off or she will be called upon to pay damages for whatever losses are sustained thereby. The Chinese government has shown itself very direlict in dealing with this boycott and the time has come on the part of this government to call a halt to all the foolish business. Just what action China may take in the matter remains to be seen, but it goes without saying that the President has determined to exercise some drastic influence, if he must, to call the yellow man back to his senses. Already the damage to our commercial interests is reported to be severe and to allow the present state of affairs to go on unchecked would be to admit ourselves wrong in the contention which the boycotters make, and also our weakness to defend our rights.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Walnuts will generally be bleached with sulphur this season, instead of by the chlorine process.

The Crafton Orange Growers Association propose to build a new packing house. unless one can be rented.

Victor Durand has fitted up a winery with a capacity for 25,000 gallons at his place in the Piner district, Sonoma county.

H. F. Thompson, of Orange, is putting up an olive oil plant on the Bixby ranch, with a capacity of 150 tons of olives per day.

Salway and Phillip peaches are ripening in Tulare county and the managers of the canneries are in need of more help to handle the crop.

At the annual meeting of the Irwindale Association last Saturday, it was voted to renew the contract with the A. C. G. Fruit Exchange for another five years.

Over five thousand boxes of peaches are in cold storage at Stockton. It is claimed peaches kept in this way can be held back from the market for three months, if necessary.

Dudley Moulton has returned to San Jose from Riverside with a large lot of scutellista, the parasite that destroys the black scale, which he will colonize in local olive orchards.

The Bellefleur apple trees are so heavily burdened with fruit at Watsonville that it may be necessary to make two or three different pickings in order to let the apples reach size in turn.

The Limonera Co., of Santa Paula, reports the sale of a car of lemons last week which netted them, f. o. b. at home, $2185. The Blanchard ranch, adjoining, also reports the sale of a car of lemons netting $2000.

About $30,000 was distributed last week to members of the Whittier Citrus Association as returns from July shipments of Valencia oranges and lemons. To date for this season the growers have received about $175,000.

The Petaluma Courier says that the average price for prunes at the canneries and dryers is way ahead of that paid last year, being now from $18 to $29 per ton, according to size and locality. The crop is better than was expected earlier in the season.

A correspondent from Toluca states that peaches from that district are being shipped to Los Angeles market, where they bring from $.75 to $1 per twenty-five pound box. Plums bring $.90 to $1.10 per box, growers receiving from $85 to $120 per wagon load.

The annual meeting of the Glendora Citrus Association was held last Saturday. The annual report showed business of the past year had been the largest in the history of the association, the returns on fruit shipped aggregating nearly one-quarter million dollars.

The Porterville Enterprise says that Los Angeles parties have about closed the deal for eighteen thousand acres of land south of Porterville, which they propose cutting up into small tracts for colonization purposes. The soil is claimed to be good for oranges, alfalfa, grain, grapes or deciduous fruits.

Walnuts will be higher priced this year than last. It is thought the association will fix the price at 12½ to 13 cents. The crop will be about one-third short, and buyers are already in the field offering 11 cents and under. The quality of the nuts will be good, but there will be more No. 2 grade than usual.

The San Antonio Fruit Exchange at Pomona recently received an average of $3.40 net per box for nine cars of Valencias. This left $3.08 per box net to the grower. This exchange received also for nine cars of lemons a total of $13,959, or $4.97 per box, to the exchange, making $.05½ per pound net to the grower.

A special rate of eighty-five cents per hundred pounds on green apples in fifteen ton lots, minimum, has just been announced by the Southern Pacific. This rate applies to apples from San Jose, Watsonville and other main line points on the coast division to all Missouri river points. The rates are made that the growers of the Coast may compete with those of the East.

Several of the largest vineyardists at Fresno have sent a petition to the Southern Pacific and Santa Fe railroads asking them to restore the rate of one and a third fares for laborers in gangs of five or more from the Bay region during the fruit season. Owing to the scarcity of Chinese and Japanese laborers in that section, this fall, the vineyardists are threatened with a labor famine and rotting of grapes from want of picking.

The Ventura Press says that apricot pits are in great demand at $7 per ton. The pits are shipped to San Francisco where they are machine cracked, the kernel is extracted and shipped to Germany, where it is made into prussic acid. The pits yield about one hundred and twenty-five pounds to the ton of green fruit. As Ventura raised ten thousand tons of green fruit, the past season, it will be seen that the pit industry is of some value.

Our correspondent, writing from Winters, says that prices on both green and dried fruits have been very good this year and crops fair, which makes times good in that section. Prices are high on grapes but the July hot spell damaged them considerably. A good deal of planting of alfalfa is being done and it will be irrigated by water from the Patah creek, which has been tapped at that point. The new cannery has been very busy and from the work done so far this, its first season, it would look as though it would be a success.

Dispatches last Saturday stated that the California Wine Association had ordered the closing out of the wineries under the control of the association about Fresno. This order affected eight large plants whose annual capacity is estimated at about $7,000,000 worth of wine. The action was claimed to be due to the order recently laid down by the Government requiring the keeping separate of the grapes crushed in making wine and brandy of two kinds. News now comes that the Internal Revenue Department has since changed their ruling and the wineries will operate this season.

AGRICULTURE.

The E. Clement Horst Co. lost three hop kilns and about 35,000 pounds of hops by fire last week.

The Anaheim cannery is running full time in tomatoes and the work will probably continue until cold weather, the crop being large and of excellent quality.

The State Horticultural Commission has liberated three thousand lady bugs in the hop yards in Sonoma county. It is expected that the lady bugs will kill the hop lice.

The hop crop about Ukiah is turning out very much better than expected. In places new hop fields will yield from four hundred to one thousand pounds an acre.

Hop picking will be in full blast in Sonoma county next week. In Mendocino county the Hop Growers' Association has decided to leave the rate for picking the same as it has been for a number of years past. Pickers will receive $1 per hundred pounds for harvesting the blossoms.

Tomatoes are bringing a fair price at Healdsburg this season at the cannery, contracts being signed at $7 per ton. The crop will not be as large as heretofore and almost the entire yield has been contracted for. The Healdsburg Fruit Association will also operate on tomatoes this year for the first time and will put up several hundred tons.

LIVE STOCK.

A creamery is to be built at Sonora, California.

The contract has been let for the equipment of the creamery to be built at Laton, Fresno county.

The Cayucos creamery commenced operations a few days ago, making two hundred pounds of butter the first day.

A party of seven dairymen from Orange county, were looking at lands near Angiola, Tulare county, last week, looking for locations.

The output of eggs and poultry at Petaluma for the past six months, as compared with last year, shows a gain of eggs, 186,293 dozen; and poultry, 1183 dozen.

Owing to the combine of the wool buyers last spring, the wool growers of Ukiah are trying to find some other method of selling their wool than by having a public auction day.

Anthrax among cattle is reported to have broken out in several farms southwest of Napa. A. Callen lost about ten head of cattle and J. Carney has lost eight head of cows. State Veterinarian Kean has placed a strict quarantine and determined effort is being made to stamp out the disease.

Simon Evinger, who has conducted the largest meat packing establishment at Fresno under the name of the Fresno Meat Co., has applied to the United States commissioner to be declared insolvent. His statement of liabilities amounts to $45,000, with assets $1741, but some creditors are secured to the amount of $19,000.

According to the Dairy Review, creameries in Humboldt county paid the following prices for butter fat for the month ending August 15th: Abrahamsen, 24 cents; Capital, 24; Eel River, 24¼; Excelsior, 24¼; Ferndale, 22, 24¼; Grizzly Bluff, 24; Pioneer, 24; Central, 24¼; Riverside, 24; Arcata Consolidated, 23; Petersen & Laurensen, 23½.

MISCELLANEOUS.

The Ukiah fair will be held this year commencing October 3d and ending October 7th.

The deciduous fruit shipments from about Newcastle will amount to nearly twelve hundred carloads for the season.

It is announced that the work of construction on the new electric road from Marysville to Grass Valley and Auburn will begin in October.

Twenty thousand boxes of Humboldt county apples are to be shipped to Australia this fall. This is the first consignment sent from that county to Australia.

The big French-Glenn ranch in Harney county, Oregon, comprising 164,000 acres, has been sold to the Co-operative Christian Federation, consideration, $1,800,000.

The attorney general of California has ruled that the State owns tide lands in Humboldt Bay, between high and low water lines, within two miles of Eureka City.

The Santa Ana Valley Irrigation Co. is preparing to increase its available supply of irrigation water by sinking new wells in the Alvarez tract at Peralta. The wells are expected to be pumping by next spring.

The official forecast of this year's State tax levy, based upon returns from the counties, places the tax rate at $.49 per $100 worth of assessed property. $.02 of this amount is on account of the State University.

It is estimated that four thousand cases of extracted honey will be shipped at Escondido this fall. Each case contains two cans, or one hundred and twenty pounds to the case, aggregating 480,000, or about eighteen carloads.

The largest single shipment of redwood ever made direct to New York and the first to go by the water route, consisting of 1,500,000 feet, is under contract to be loaded at Eureka by the middle of November and delivered in New York by April.

The Santa Paula Chronicle says that W. H. Allen took four hundred colonies of bees into the mountains last March, since which time he has increased his colonies to six hundred and thirty and extracted fifty-three tons of honey, worth five cents per pound.

A schooner loaded with codfish from Alaska arrived at San Francisco last week. The success of the experiment of bringing the codfish to San Francisco for curing it is claimed will develop into an industry as great as the codfisheries of the eastern coast.

The Bay Cities Water Co. has offered to sell to the city of San Francisco its water site, located high up in the Sierra Nevadas, for $9,105,000, and the total cost of transmission, including a distributing system in the city, is to be $38,483,700. By the acquisition of this system the city would be provided with a supply of water large enough for the needs of 3,500,000 people.

C. H. SESSIONS, ASSOCIATE EDITOR

THE DAIRY COW.

Someone has said that a cow "is partly born and partly made." We hear a good deal about feeding and we hear a good deal about breeding, and the advocates of each claim for them about all the virtues that are discoverable. The fact is, however, that it is a combination of the two that will produce the kind of cow we must have. It is the combination of the two that has produced the cow we now have, whether she be good or bad.

A naturally poor dairy cow badly fed will prove continuously unprofitable. A poor dairy cow well fed may yield a small revenue. A good dairy cow badly fed will produce only a little revenue, and it is probable that she will never have her full capacity developed. One of the things that has been brought out by good feed is that many cows that were supposed to be poor cows were simply cows that had been always so poorly fed that they had never had their full capacities developed.

The man that is bright enough to study breeding till he can get a herd of highly-bred cows, and study feeding till he can get every cow to giving milk to her full capacity, is the man that will make money out of his dairy herd.—Farmers' Review.

DAIRY STEERS.

Dairy cows have for centuries been bred and trained for large consumption and assimilation of feed. They are relatively larger feeders and producers than the beef breeds. Loretta D., the champion cow at the St. Louis dairy cow demonstration, consumed daily 25.34 lbs. of digestible matter per 1000 lbs. live weight, while the average capacity of the beef breeds is only about 13 lbs. She yielded 6.69 lbs. of milk solids daily, or 1 lb. to 3.4 lbs. of nutriment consumed. Add to the milk solids yielded the daily gain in weight her daily product during the demonstration was equivalent to a gain in weight of 10 lbs. per day. This shows what wonderful powers of feeding and assimilation have been developed in the high type dairy cow. That she transmits both her feeding capacity and assimilating powers to her male progeny is becoming apparent in feeding experiments with dairy steers.—Iowa Homestead.

THE PACKER'S PROFIT.

Referring to the profit which packers make in slaughtering which might be made by individual farmers, in some cases at least, the Orange Judd Farmer gives the following interesting figures:

"Take a hog weighing at home 200 pounds on a basis of a 5 cent market. live weight. Its value is $10. If fat, the hog loses about 20 per cent, or forty pounds, leaving 160 pounds edible portion. Approximately the dressing will be: Two hams, thirty pounds; two shoulders, twenty-four pounds; four strips bacon, twenty-eight pounds; spareribs, head, feet and backbone, thirty-five pounds; leaving about forty-five pounds for sausage and lard. The meats to be smoked will increase about 10 per cent in weight in the pickle, but lose about the same in smoking, so the selling weight is the same as the dressing weight. The following are conservative prices for a country dressed hog: Thirty pounds ham at 14 cents, $4.20; twenty-eight pounds bacon at 15 cents, $4.20; twenty-four pounds shoulder at 9 cents, $2.16; fifteen pounds lard or sausage at 12½ cents, $5.60; thirty-five pounds backbone, spareribs, etc., at 6 cents, $2.10; scap fat about 25 cents; total, $18.51; cost of hog, $10; profit, $8.51."

Not all of the profit is given in the above, for there are the bristles and the tankage, glue and fertilizer.

HOLDING BACK MILK.

According to Professor Stewart, the following is the explanation why cows sometimes hold up or keep back their milk. The production of milk is due to a nervous action by which the gladular substance of the udder is broken down into milk whenever the cow is influenced by sufficient excitement of the right kind. It depends upon the structure and function of the udder just as much as the sections of other glands do, which we know are wholly subject to a set of nerves controlling this distinct function. The udder is not a mere vessel for holding milk that is supposed to be secereted continually and gathers in the udder, as one may suppose a constant dripping of any fluid would fill any other receptacle. On the contrary, it is a gland, made up of cellular substance, which grows by separation (from the blood) of the matter required. When it has attained maturity, or when the necessary nervous action occurs, it breaks down into a special product—milk.

Several experiments have been made with the udders of cows in milking condition that have been slaughtered, and an examination has been recorded of the udder of a cow accidentally killed on the railroad when going home to be milked, when she would have given the usual ten quarts. The microscope showed the minute globules of the tissue swollen and distended, but the udder contained practically no milk, except a very small quantity that drained from the divided tissue when cut across.

We perceive that this function of the cow is wholly nervous in its action, as, indeed, every other function of the animal is, and if the due nervous excitement is absent, there is no functional action. It is wholly due to the right influence on the nerves that the milk is produced and flows from every ultimate globule of the udder down through all the ducts, small and great, to the teat. Then, if all goes well, and the cow is in her natural, easily excited, nervous condition, as soon as the milker begins to touch

Washed in 1 minute

A Big Difference

One Minute's Washing as compared to at least fifteen. Wouldn't you like to save at least fourteen minutes twice a day? **One minute** with a cloth and brush cleans the absolutely simple Sharples Dairy Tubular Cream Separator bowl shown in the upper picture. It takes fifteen minutes to half an hour with a cloth and something to dig out dents, grooves, corners and holes to clean other bowls—one of which is shown in lower picture.

Count the pieces — notice the difference—and you'll understand why the one who has to do the cleaning prefers the simple Sharples Tubular.

There are other advantages just as much in favor of the Tubular. Write today for catalog V-260—it tells you all about the gain, use, and choice of a separator.

KILLING BEEF.

It is important that an animal intended for slaughter should be kept off feed from twenty-four to thirty-six hours. If on full feed the system is gorged and the blood, loaded with assimilated nutrients, is driven to the extremities of the capilaries. In such condition it is impossible to thoroughly drain out the veins when the animal is bled and a reddish colored, unattractive carcass results. Food in the stomach decomposes very rapidly after slaughter and when the dressing is slow the gases generated often flavor the meat Water should be given freely up to the time of slaughter as it keeps the temperature normal and helps to wash the effete matter out of the system, resulting in a nicely colored carcass. The care of animals previous to slaughter has considerable effect on the keeping qualities of the meat. It is highly important that they are not excited in any way sufficiently to raise the temperature of the body.

Excitement prevents proper drainage of blood vessels and, if extreme, will cause souring of the meat very soon after dressing. In no instance should an animal be killed after a long drive or after a rapid run about the pasture. If heated by such causes it is far better to allow it to rest over night before killing than to risk the meat spoiling. The flesh of an animal that has been overheated is usually a pale color and very often develops a sour or putrid odor within three or four days after being dressed. It is also essential that the animal be carefully handled, so as not to bruise the body. Bruises cause the blood to settle in that portion of the body affected, presenting an uninviting appearance and often cause the loss of a considerable part of the carcass.

A thirty-six hour fast, plenty of water, careful handling and rest before slaughter are all important in securing meat in the best condition for use, either fresh of for curing purposes. When much meat is prepared for use on the farm it will be best to provide such tools as are necessary for the rapid prosecution of the work. A 7-inch curved skinning knife, an 8-inch straight sticking knife, a 14-inch steel, a 28-inch meat saw, a candle-stick scraper and an ax are all the tools really essential to rapid dressing. Some means of raising the carcass up from the ground or floor and a place to hang the lighter animals should be provided. What these arrangements shall be depends largely on the amount of work to be done and the circumstances. A block and tackle with 6-inch pulley will answer the purpose very well when they may be had and a suitable place is at hand for suspending them. Age affects the flavor and texture of the meat to quite an extent. While it is not possible to state the age at which an animal will be best for meat it is a well-known fact that meat from old animals is more likely to be tough than that from young ones. The flesh of very young animals frequently lacks flavor and is watery. An old animal properly fattened and in good health is preferable to a young one in poor condition.—The Ranch.

The number of flies on a farm can be kept in check by keeping all manure carted away to the field, thus removing their breeding grounds. Some day this will appear more important than now.

SHEEP NOTES.

Ewes will not breed well when too fat.

Give the lambs a little milk feed at time of weaning.

Sheep are unharmed by intense dry cold, but cold rains are injurious.

The greatest profit in feeding sheep for mutton is gained while the animals are young.

At no time should sheep be crowded and especially while eating any kind of food.

Wool is that farm product which brings the most money in proportion to what it takes from the farm, and with the least labor to the producer.

Using the improved breeds for crossing means that a larger allowance of food must be given if success is expected.

While the sheep are on a good pasture, cull out the flock, and fatten off all sheep that fall below the proper standard of excellence.

All things considered, a three-year-old ram is best to use in a flock that is being graded up. Age gives strength to the progeny and this is an important item with sheep.

Better sheep will grow more pounds of wool than are now obtained and at the same time grow a carcass improved in the essentials to profitable mutton productions.

Particular attention should be paid to the securing of a thoroughbred ram possessing good qualities, as upon his excellence will depend the future value of the flock and he should be changed every two years to prevent inbreeding.

Sheep will take the place of swine on the dairy farm and dispose of the by-products to as good advantage as pigs, while the difference in the tidiness and sanitary conditions existing with the two classes of animals in many cases can be easily imagined.

LESS FEED WHILE IDLE.

The horse not only requires less feed when idle than when at work, says Andrew Stenson, but is actually injured if the ration is not reduced on days of idleness. Some feeders of high standing reduce the feed of their work horses on Sundays and holidays, in the belief that even one day's feeding of a working ration while the horse is at rest is injurious. It is now the belief of all who have thoroughly studied the subject that idle horses are fed too heavily as a rule. But no fixed ration can be named, since the food requirements of individual horses differ so widely. Close observation will enable the feeder to adapt the quantity to the needs of each animal.

Don't believe all you hear; but be sure to believe all you say.

VETERINARY DEPARTMENT

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease ap eared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W. J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

POSSIBLY GLANDERS.

Editor Cultivator: I would like to have you tell me what is the trouble with one of my horses and what to do for her. About six or eight weeks ago I began to notice her throat being puffed up between the jaw bones in the mornings. Not a hard swelling, but soft. After eating and exercising, or working, it all goes down, to be repeated the next morning. She is not a very hearty drinker, but she eats well, but is getting very thin. I grain her and feed good barley hay. I have looked for beards in her mouth, but can see none. She seems to feel well, but is slow; from loss of flesh, I think.—S., Santa Ana.

You didn't state whether the horse has any discharge from the nose. The symptoms you describe are those of glanders in the first stages. You had better call in a qualified veterinary surgeon, and have him make a close examination, and if necessary test him with Mallien. A horse in the condition you describe should not be treated without a thorough examination.

HUGE WYOMING DAM.

(Continued from First Page.)

Simply that the nation has wisely decided to use the money derived from the sale of western public lands to make its desert soil of value and furnish many home-building opportunities. It means that many men will find employment in in the construction of dams and canals in every western community, and that finally as the works are completed, one by one, new farm homes will be established, adding to the nation's wealth and balancing our population now inclined cityward.

The Lloyd Co., Inc.
Petaluma, California

For a thousand years longer this splendid dam site would likely stand idle before private capital would develop it to its magnificent full capacity, for the difficulties in the way of the engineers are many and unknown; but the government will meet all obstacles and overcome them and finally turn over to a thousand farmers a perfect job of engineering, comparable to the great works of the Peruvian Incas, the Egyptian Rameses or the British engineers of India—an enduring monument for all time to the wisdom of the present generation of Americans.

NATIONAL IRRIGATION CONGRESS

The session of the National Irrigation Congress, held at Portland, Oregon, last week, was perhaps one of the best attended, most interesting and possibly stormy meetings ever held.

This session of the congress was important for the pronounced stand assumed on three subjects.

It declared emphatically that its sympathy is with the small land owners against the large landed proprietors who seek to have the national irrigation law so amended as to permit the retention of more than 160 acres of irrigated land.

The congress also expressed the opinion that Government enterprise in the work of reclaiming arid lands should not unnecessarily interfere with previous enterprise, nor private enterprise with prior government projects.

Finally, it expressed disapproval of the repeated attempts to inject the subject of undesirable foreign immigration into its deliberations, contending that this subject is one in which the congress, as a body, is not interested.

Owing to the impracticability of securing the attendance of the delegates in sectional meetings the congress changed its constitution so as to provide that at future assemblages a general session shall be held each day of the convention period.

Gov. Geo. C. Pardee, of California, was re-elected president of the congress, and Boise, Idaho, was chosen as the next place of meeting.

Resolutions.—In substance the resolutions adopted by the congress follow:

Indorsement of Statehood for the Territory of New Mexico and joint Statehood for Oklahoma and Indian Territory. The congress believes that too much capital, public and private, cannot be invested in the reclamation of arid lands, and therefore declares that the Government should not unnecessarily interfere with or prevent private enterprise from building reservoirs and other works for reclaiming arid lands. Another resolution of much the same purport declares that Government as well as private enterprise should both be extended to the utmost, and believes that Government enterprise should not unnecessarily interfere with private enterprise, nor should private enterprise unnecessarily interfere with or prevent Government enterprise from building reservoirs and other works for reclamation of arid lands. In order to encourage beet sugar production in the United States, the congress asserts its opposition to the granting of further concessions to tropicalists, and the resolution advocates Federal legislation in behalf of the industry. It is the opinion of the congress that the national irrigation law should be so extended as to include the State of Texas within its provisions. As confusion is said to exist in the minds of many people on the subject, the congress declares that there is not, nor has there been, any connection between the National Irrigation Congress and the National Irrigation Association.

The congress also favored the early reclamation of small tracts of land whenever the cost per acre of reclamation does not exceed the cost per acre of larger enterprises of similar character. The Federal Congress was urged to enact such laws as will enable the National Government to exercise the right of eminent domain when necessary to carry out the purposes of the national irrigation law. The congress indorsed the effective and business-like administration of the Forestry Bureau, the efficiency of the work of the Reclamation Service, but recommended that the Reclamation Service and its representatives cooperate with State officers in matters affecting the State's landed interests. The resolutions commended the work of the experiment stations of the Department of Agriculture, and the United States Weather Bureau for its assistance to the Reclamation Service.

CLIMATE AND CROP REPORT

The weather and crop conditions for the week ending August 30, are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—Clear and warm weather prevailed most of the week in all parts of the State, with less than the usual amount of fog in the coast districts.

The grain and hay crops are nearly all secured, though in some sections thrashing and baling are not yet completed. The hay crop is the best for several years in nearly all parts of the State, but the grain crop as a whole is quite disappointing and considerably below average. Barley has turned out very well in most sections and wheat is a fair crop in places, though a failure in others. Oats are exceedingly light. Harvest continues on the heavy crop of sugar beets. Beans are rapidly ripening and in some sections the prospects are good for a very large yield. Hops are maturing and picking is in progress; reports as to the yield are conflicting, but a fair crop is probable.

Grape picking is progressing rapidly and raisin making has commenced. The yield of grapes will probably not be as heavy as estimated a few weeks ago, owing to extreme heat in July and a few days of this month, but in many sections the crop will be fully average. Many varieties of table grapes are in the market and they are of excellent quality. The deciduous fruit crop is being rapidly gathered and much of it has been secured. Citrus fruits are in excellent condition, and it is estimated that the orange crop in Southern California this season will be the heaviest ever harvested; large crops are also expected in the Porterville, Oroville and Cloverdale districts. Walnuts, almonds and olives are in good condition; almond picking has commenced.

Eureka Summary.—Foggy mornings along the coast. Continued clear and warm in the interior. Oats are being harvested with good results. Barley is very promising. Worms still doing damage to peas and beets on the bottom lands.

Los Angeles Summary.—The week closed clear and warm, with severe thunderstorms in the San Bernardino mountains and heavy rain. Threshing continues. Sugar beets are being harvested.

Auction Sale

37 Fine Milk Cows, 1 Holstein Bull

AT COMPTON

2 blocks West of Long Beach Electric Line
1 block West of High School Building

Thursday, September 7th, at 10 a. m.

I will sell my entire herd, consisting of 37 head Holsteins and Durhams Except 5 wich are first class Jerseys, and all are as fine milk cows as can be found in the country.

These cows are all large milkers, in good condition, many fresh or coming in soon, and will be sold without reserve or limit, as I am quitting the dairy business, and will make a genuine closing out sale. Buyers in need of first-class cows cannot afford to miss this sale.

Terms: Six months time will be given with note and approved security.

Free Lunch at noon.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

DRY FEEDING.

(2nd Chapter.)

Dr. H. P. Nottage, of Goshen, Mass., describes his new method as "A New, Practical, Labor-Saving, Profit-Earning Method of Feeding." His article would be too long for our columns, so I will give extracts from it.

* * *

What It Is.—By "dry feeding" I understand that no mashes, hot or cold, are fed. This does not rule out dry combinations which have been called "mashes" by some, but which should be called mixtures, for the term "mashes" is understood by the poultryman to be a mixture of several kinds of grain, green stuff and animal food which has been subjected to the action of moisture, and in many cases also to heat. Nor does it rule out chopped or shredded green stuff, such as onions, beets, etc., fed separately. In a broad sense it is the feeding of uncooked food to poultry, and more especially food that has not been moistened. To be practical, let us see what advantages the dry feeding can show.

* * *

Advantages.—The question is by no means settled and it will require long and careful experience by observant poultrymen and scientific experts before it can be demonstrated whether dry feeding should supplant or supplement the wider and better known method of feeding wet mashes in addition to dry grain.

In the meantime, however, some results obtained by dry feeding have forced themselves upon the attention of poultrymen, and the subject is beginning to receive more consideration than formerly.

Each observer should ask himself why he changes his manner of feeding to a method that as yet has only a few strong advocates. Does he expect to get a few more eggs by doing this? Better attempt this by breeding from good layers; for it is not yet proved that dry feeding produces more or fewer eggs. Does the routine work of mixing and cooking the mash take up too much of your time? It is my experience that you can give it up and get just as good results. Do your hens have symptoms of cholera or bowel looseness of a mild degree that makes the dropping-board hard to clean? Come and see the roost platform in my houses, and you will find them always dry and smooth with only an occasional spot.

* * *

The Method.—To understand better the advantages of dry feeding, let us look at the method that I employ in using the grains. The fact that I have gotten rid of mixing and cooking mashes and am now feeding the most of the grain for the greater part of the time from feed boxes, shows how much easier it is to care for a good sized flock of fowls. The advantages are apparent to all who feed their flock four or five times a day, and constantly fuss with them. I have come to be known by the farmers around here as "the man who feeds his hens twice a week," from the fact that during the growing period from the incubator to the pullet who is getting ready to lay, I feed all my grain and beef scraps from feed boxes which I fill up twice a week. Bear in mind that all young stock is on free range and laying birds in yards so large that they seldom wander to the ends of them; also that even this stock is let out to run at large on alternate days.

I would not advise changing suddenly any method of feeding, as it will seriously affect the egg output for a time; but after a while the hens will lay as before. The best way is to begin with the chicks right from the incubator. Looking at the subject of feeding from the beginner's standpoint, I am certainly convinced that fewer mistakes will be made and a larger number of chickens raised to a healthy maturity by feeding dry grains and beef scraps from feed boxes constantly filled, provided the chicks can run upon grass. There will be seen no rushing, trampling crowds of chicks; but a contented and lively set of youngsters that are plump and happy, although on free range where some people think they are likely to run the flesh off their bones; they will find time to dig holes in the dirt, lie under the shade of the trees and enjoy life. He will be surprised at the rapid growth of his stock, if it has any "grow" in it. More of this when we speak of results. Do not get the idea that an experienced poultryman cannot produce like good results with his mashes; for he certainly can. However, let a beginner start with mashes and they will often become "messes" and more chicks will drop out of the race than if he adopts the plan I pursue with mine.

* *

My Plan—Have plenty of grit where the chicks can pick it up for their first meal. Get your miller to mix together one part of wheat to two parts of corn and crack them so they will be a little finer than cracked corn. Place a heap of this in front of the brooder, and beside it a heap of dried beef scraps, with the coarser portion sifted out until the chicks are big enough to eat the scraps as they come to you. If you have any skimmed milk keep the youngsters on that for a drink, or you can let them have their choice between milk and water. If there is not a green sod for them to pull at when they get into their second week, chop up some onions, or lettuce or cabbage, and let them have some once a day. Get them out on the ground as soon as a green blade of grass can be seen pushing up through the old sod.

You can now let them have only this mixture of grain, and the beef scraps from the two compartments of a feed box until the young pullets are ready to go into winter quarters, provided they are upon grass all the time. In this way it is possible to grow good healthy layers and not have to fuss about "balanced rations" and forty different kinds of food.

When the pullets show signs of get-

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

When writing advertisers mention Cultivator.

ting ready to lay, which they should do about September if they are hatched in March, or the first of April, it is high time to get them into the quarters they will occupy during the winter. It is now time to change your manner of feeding somewhat.

Right here let me say that I believe I have learned that it pays to have dried beef scraps constantly before the fowls, summer and winter. You can vary this, if you want to, by feeding green cut bone occasionally, but my hens would just as soon have the scraps. I have seen them nibble delicately at green cut bone, showing that the craving for animal food was fully met by the scraps fed in this way.

* * *

Balanced Rations.—Each hen eats what she wants, and what she wants is usually what she needs. If you put a definite amount of animal food in a mash, some hens will not get enough meat and others will over eat. I am surprised to see how little meat they eat when it is fed in this way, yet it appears to be all they need. Just as soon as insects begin to be scarce the meat box will show it, for the hens balance their rations so far as this is concerned. Last year they laid more eggs for me than when I put the meat in a mash, and at no time have they averaged less. Leave then the beef scraps in the feed box and take out the grain, just noting how much grain your flock is eating every twenty-four hours. Put litter in the pens and feed the same amount of grain at different times during the day in this litter. It is time now to add oats to your bill of fare if you have not already done so.

When freezing weather begins, oats, corn and wheat in alternation are fed in the litter at 4 p. m., and after the fowls are on the roosts for the night. They find this latter feed when they come off the roosts, and I find a big cloud of dust and a lot of active, cackling hens when I open the doors in the morning. At noon they have green food, sugar beets split in halves and a head or two of cabbage thrown into each pen. When the litter is pretty well broken up a forkful of Japanese millet, stalks and all, or clover rowen, or buckwheat is thrown in to replenish the litter.

By this method of feeding from the first day of the chick's existence, you will find that the big chicks and the little ones can run together and all get enough to eat. I don't advocate the mixing of chicks of all sizes, but it is wonderful what grain in a feed box will do to rectify the mistakes of beginners, especially when they let all sizes of chicks run together.

* * *

The Results.—I have noticed that I get more eggs from the same number of birds than when I fed mashes. Some of this may be due to selection in breeding, but I believe that also some of it is due to the fact that my birds have not had a day's check to development. I do not think it is good policy to keep a hen always hungry, but rather to keep her so that while you know she is well fed she will be ready to hunt for more.

Continuous growth, higher average weight, constant laying when through moulting, until she wants to take a rest and then I let her stay broody for a while; vigor of stock, early maturity—these have been the results that have followed me since I adopted this way of feeding. Certainly I have not lost much.

Much less drudgery; hens that are plump, but not baggy; always active in spite of an open feed box; these things also have been noted. As for rapidity of growth, although I have adhered closely to the above program and made no attempt to feed especially for broilers, I nearly always get them to weigh three pounds to the pair in eight weeks.

* * *

We have still to hear from Mr. P. R. Park and Dr. Sanborn of their methods and the results in our chat next week.

(To be continued.)

* * *

EDITOR'S QUESTION BOX.

Kerosene Emulsion.—(W. A. L.): Will you please give the recipe for kersene emulsion for "chicken dip." I have seen it twice in the Cultivator, and the second time was different from the first. I don't want to get it too strong. How do you get it into the feathers on the head?

Answer.—The full directions for dipping chickens and exactly how to make the dip you will find in the Cultivator of July 7th, page 16. If you have mislaid it by writing and sending stamps to the office a copy will be sent to you.

* * *

Apoplexy—(Mrs. F. A. R.): One of my Brown Leghorn hens died very suddenly, apparently from having a fit. Her neck was drawn back very tightly and she died about half an hour after I noticed the first symptom.

The hen was confined in a coop with eleven little chicks two days old, and had been fed wheat, leaves from green corn, and the chicks bread softened with milk, but on making a post mortem examination we found her crop empty—also all the intestines. Plenty of grit in the gizzard, and the hen was quite fat. She seemed to have a high fever and apparently had starved to death, but her chicks were well fed. We are at a loss to know what caused her death and what remedy to use in case another hen should act the same way.

Answer.—Your hen died of apoplexy. Apoplexy may occur from over-heating or sunstroke, overfeeding, over-exertion, fright from being chased. I have seen birds so affected from the bite of a tarantula in Oklahoma. I gave aconite one drop in a teaspoonful of milk with good results. Congestion of the brain has similar symptoms. As treatment apply cold water or ice to the head and give half a teaspoonful of Epsom salts.

* * *

Roup.—(W. W. B.): I am having trouble with my chickens, mostly the Leghorns. As you have helped others, it may be that you can help me. They start in occasionally shaking their heads and at the same time giving a "Wha!" followed by working their tongue as if in the act of swallowing; as the trouble advances there appears to be difficulty in breathing—opening their mouths and extending their necks when breathing. First, I should like to know the cause and then the cure for the trouble. I have examined their throats and can see nothing abnormal. They eat well, but are dumpy. What has become of all the Buff Orpingtons? I do not find any advertisements in the Cultivator, and I want some "new blood" this fall. What is your idea of the Orpingtons as a general purpose fowl?

Answer.—The sypmtoms so far as you describe them are either roup or gape worms. Kill the worst case and hold a post mortem examination. Carefully cut open the windpipe and see if you can find any little worms hanging on to the sides of the wind pipe, then you will know for sure.

In any case you can give the affected birds a two-grain pill of assafoe-

THE JUBILEE POULTRY JOURNAL

A "Worth-while" Journal devoted to the Poultry Industry of the Pacific Coast. A Journal radically different, up-to-date and aggressive, advocating the cause of Better Poultry and More Profit.

Unusual contributions of great value, unusual competitions designed to stimulate, cultivate and educate the poultrymen to reach a greater success,—it is "Worth while," worth YOUR while and you should subscribe.

tida night and morning, and if it is roup, which I think it is, give in addition the following: Mix two table spoons lard, one of red pepper, one of dry mustard, one of vinegar, add flour till the whole has the consistency of dough. Roll into slugs the size of the top joint of your little finger for adult hens, smaller for young chicks. One or two doses twenty-four hours apart usually effects a cure.

Buff Orpingtons are good general purpose fowls. They lay a brown egg and have white skin, but are excellent table fowls. There are quite a number of Buff Orpington breeders in the country. Watch our advertisements.

* * *

Buff Orpingtons—(Subscriber): Will you please tell me through your paper where I can get Buff Orpington chicks just hatched; also a good plan for hen house? Is it advisable to have them roost and lay in the same house.

Answer.—I am sorry I cannot tell you where you can find Buff Orpingtons just batched at this season, moulting time, but if you watch our advertisements, you will see them at the hatching season.

As for plans of a house, I do not know what kind, what price, for what breed, nor anything about your accommodations, so would not venture an opinion. Fowls should never have their nests inside the roosting house in this climate.

* * *

Insufficient Grit.—(Constant Reader.): Found one little B. Leghorn, a fine layer, suddenly taken very ill, killed her, found half of a large safety pin in her gizzard, piercing it. Found one old White Leghorn drooping and could not stop her passing grain whole. Found half gizzard packed full of a ball of adobe. The other half distended to abnormal size and soft. So goes!

Answer.—Insufficient sharp, hard grit. Your post-mortems have proved beyond doubt what is the matter. Supply your fowls with proper "hen's teeth" without delay or you will lose others.

SCALY LEGS.

From a bulletin of the New Mexico College of Agriculture we note:

Scaly-legs is a trouble which is caused by a mite which burrows underneath the scales of the feet and legs causing an irritation which results in a multiplication of the cells of the epidermis, and, therefore, a much thickened scale. To successfully treat this disease the scales must first be removed so that the medicine can come in contact with the mites. The legs must be soaked in soapy water until the scales are soft, when they may be removed. Dry thoroughly and treat with the following: Balsam of Peru, two drachms to one ounce of vaseline. Mix thoroughly. The disease readily yields to treatment if the first step, that of removing the scales, has been properly done.

SEPARATING POULTRY.

Upon almost all farms it is customary to see the chickens of both sexes running about together, and little attention seems to be paid to the fact that when pullets and cockerels are separated both thrive infinitely better. Of course, keeping them apart may involve a certain amount of work, but any extra labor is well repaid by the improved growth and the better stamina of the chickens of both sexes.

There are several reasons for advocating the separation of the sexes at as early an age as possible, and it will be found that both the cockerels and pullets thrive much better when such a plan is adopted. When they are permitted to remain together the cockerels will worry the pullets a good deal, besides which they will fight among themselves for the mastery of the yard. When cockerels are by themselves they will all live in peace, and little difficulty will be found in keeping large numbers together; but, on the contrary, when there are any pullets present they will fight, frequently causing one another a great amount of harm. Especially is this the case with birds that are to be kept for stock purposes, as should the comb or wattles become damaged or deformed through fighting, it may seriously affect their sale. It is important to separate the sexes immediately they are large enough to be distinguished, because once the cockerels have commenced fighting they will continue doing so, even after they have been taken away from the pullets.—Farm Home.

While crate fattening is producing satisfactory results, and increasing in popularity, the machine method of cramming fowls is growing less popular, even in the European countries where it was practiced extensively a few years ago. We are reliably informed that English market poultry men who tested thoroughly the enforced fattening of fowls by the use of the cramming machine have one by one abandoned it in favor of the more natural method of crate fattening The same is true of Canadian poultry men. The experiments made thus far in this and other countries have not borne out the claims of the cramming process enthusiasts. On the other hand crate fattening can be practiced conveniently and without much additional expense by market poultry men and farmers generally, and as the results seem to be quite satisfactory, we look for a rapid growth in the popularity of this plan of improving the fowl.

This is the time of year when lice get in their deadly work in the poultry yard; more chicks are killed by lice than through all other chicken ailments. The young chicks should be examined every week or so for head lice and lice on the body. A good dusting with insect-powder is usually sufficient for the body-lice; for head-lice, grease their heads with carbolic salve. The laying hens, if they have not been properly cared for, will be found to be teeming with lice. Spray the roosts and nestboxes with a coal-oil emulsion or some liquid lice-killer. If the lice are very numerous, it may be necessary to dust each one separately with insect-powder before the lice can be effectively exterminated.

PETALUMA'S FAMOUS POULTRY SUPPLY HOUSE

Retail Department of the Coulson Poultry and Stock Food Co.

INTERIOR VIEW OF STORE AND SHIPPING DEPARTMENT OF COULSON'S POULTRY AND STOCK FOOD COMPANY.

The feeds are prepared on lower floor, and after they are all prepared, are sent up to the shipping department by means of two electric elevators, and all day long the men wheel out truck load after truck load of Coulson's Egg Food and Coulson's Chick Foods—hundreds and hundreds of sacks, going to many different destinations—some going hundreds of miles south, some hundreds of miles north, some way east, and some across the water to the islands. Truly, it is a wonderful business, and it certainly must be a good feed. Coulson's Chick Feed, Coulson's Egg Food for Laying Hens, Coulson's Molting Food, etc.

Petaluma, California, known as the Egg Town or the White Leghorn City of the World; called so because of the millions of White Leghorn Chickens raised around there.

PETALUMA, CAL., is known as the greatest poultry center in the world. There are chickens by the million—nearly everybody for miles around is engaged in raising poultry. In taking a poultry census it was found that there was at one place, 35,000 laying hens in one square mile, and taking in a radius of 12 miles around Petaluma, there are about one million laying hens. There are many large poultry farms of 200 and 300 acres, and they will have from 3000 to 6000 laying hens, and they gather in eggs by the thousand.

There was shipped out from Petaluma, during the year 1903, 3,407,334 dozen eggs, and during the year 1904 three and a half million dozen, and, this does not include the millions of eggs that were placed in incubators, for there are hundreds and hundreds of poultry farms near Petaluma, and all have their incubators. Some have incubators to hatch out over 5000 chicks at a time, and on some places they will hatch out from 20,000 to 50,000 chicks, or more, each season.

To feed all these chickens it requires about 5000 tons of feed per month. This feed is brought in by railroads, boats and steamers. The Coulson Co. mix these feeds together, using certain proportions of each kind, so as to make a balanced ration, or proper feed for the fowls. The mixed feed for laying hens is put up in feed bags and is called COULSON'S EGG FOOD. Two kinds of feed is prepared for little chicks. The cheapest kind is made of ground grains and animal meals, and is called Coulson's Growing Chick Feed, and the best kind is COULSON'S SPECIAL Chick Feed, which is all granulated pieces of cracked grain, seeds, and tiny pieces of dried meats, granulated bone, etc.

The Coulson Co. is supplying the feed for these large and successful poultry farms, and, of course, it must be the best feed to produce such good results. Coulson's Poultry Food is now shipped to all parts of the Pacific Coast. Ask your feed dealer about it.

ANOTHER VIEW OF RETAIL DEPARTMENT OF COULSON'S POULTRY SUPPLY HOUSE.

Coulson's No. "3" Condition Powders for poultry—some for hens, some for little chicks, some for horses, some for stock of all kinds. Incubators, Lice Killers, Sprays, Disinfectants, Poultry Remedies, Roup Cure, Cholera Cure, Remedy for preventing little chicks from picking each other, etc.

If you want some good things to help your fowls, we can supply you. Send for our catalogue and let us hear how you are getting along with your poultry, chickens, turkeys, etc. Write to us now, while you think about it.

The home of Coulson's Poultry Food Co., showing exterior view of factory building on upper Main street, opposite the beautiful plaza.

Notice the big truck loads of Coulson's Egg Food and Coulson's Chick Food and also the hundreds of sacks piled up on the sidewalk ready for shipment and still more to come, for there are from 330 to over 400 sacks in a carload, and shipping 2 or 3 carloads in a day is common.

Feed your hens Coulson's Special Moulting Feed and you will have splendid success.

If you want to buy any feed, poultry supplies, incubators, condition powders, roup cure, lice killer, spray pumps, etc., send to Coulson Co We can supply you at lowest prices.

Coulson Poultry and Stock Food Co., 730-732 Main Street Petaluma, California

Queries and Suggestions

JOHNSON GRASS.

Editor Cultivator: I have frequently noticed articles about the so-called Johnson grass, and they almost universally condemn it. Editors who know nothing at all about it personally seem to think it a safe subject to write about, supposing it has no more numerous friends than has Judas Iscariot.

I know it is generally considered a nuisance, and so it is if you allow it to take root in damp land, where you don't want it. I have been familiar with it ever since it was first introduced into this country. I consider that when it is rightly handled it is a very valuable plant to be used on naturally dry land under irrigation. The article from the Fresno Republican which you reproduced August 18 is the merest rot. Pastures in this locality have contained Johnson grass for years, and all kinds of stock eat it as readily as they do alfalfa. Of course if it is allowed to get ripe and hard, it is no better than alfalfa that has become woody. It rivals alfalfa in growth and is more tenacious of life. You can pasture it close all summer, then you can plow it in the winter and the succulent roots furnish an amazing amount of very fine food for hogs. I have seen hogs fat enough for market with no other feed. In the spring you have only to harrow it down, give it a chance, and you still have a good stand and a fine pasture.

There is no danger of its spreading on dry land, either from the seed or roots. Don't plant it in your orchards if you don't want it there, for the moisture your trees require is sufficient for it, and it will hold its own with any orchard I ever saw.—E. A. May, Poplar, Tulare Co.

BASKET WILLOW.

Editor Cultivator: Wishing to plant some basket willows, I write to ask if you can tell me where I can get cuttings of some. Any information on the subject will be appreciated.—E. D. Linder, Santa Ana.

The best willow for basket work which can be grown in California is Salix viminalis. The only place we know of its being for sale is the Fancher Creek Nurseries, Fresno.

BELGIAN HARES.

Editor of Cultivator: Please tell me where I can buy Belgian hares.—W. Robinson, San Bernardino, Cal.

The Belgian hare breeders are not as plentiful as they were at one time, so we do not have the address of any one able to supply stock at this time. As interest seems to be increasing it may be possible that breeders will find profit in carrying a card in the Cultivator.

STRAWBERRIES—RHUBARB.

Editor Cultivator: I want to have a few Arizona Everbearing strawberries in my yard; please tell me when to plant, and how to cultivate for berries next spring. Please tell me, also, if I can grow a small quantity of Burbank's Crimson Rhubarb, or does its cultivation require a large space. I am inexperienced, but think I can learn.—Mrs. A. L. H., Mesa, Arizona.

Strawberry plants may be set out at almost any time from fall to spring, if in a location where the soil is warm and drainage good. If these conditions are not present, it is not a good place for strawberries. The secret of success lies in freedom from weeds, frequent watering and cultivation and the retention of soil moisture close to the surface. This latter, while attained in commercial fields by frequent irrigations and cultivations, may also be produced by a good mulch between the rows and right to the roots of the plant on all sides. Keep off runners unless you wish more young plants. You may easily grow the Crimson Winter Rhubarb in a limited space.

REMOVING OLD VINES.

Editor Cultivator: Will you kindly inform me through the columns of your valued paper, the best way for me to get rid of several hundred grape vines which are planted in a young walnut orchard and are sapping the moisture from the ground and retarding the tree growth. They are Muscat, and Tokays, four and five years old, and very stocky.

Will chopping them off at several inches below the surface kill them, or will the roots sprout? What time of year would be best to cut them out?—C. H., Pomona.

We do not think it will do well to chop off the vines as you suggest, for it would certainly prevent deep cultivation for many years, and besides the continually sprouting, would make additional work. We believe the advantages secured by removing the old vines will be such as to compensate for the additional expense. The following contrivance, which has been used, accomplishes the removal of vines the most cheaply of any of which we know:

Take the rear axle and wheels of a good stout wagon and a straight grained pine four by four, and say sixteen feet long. Fasten to center of axle with about two and one-half feet projecting to the rear. On this short end of the lever have a blacksmith construct a stout hook. Then run the trucks over the row of grape vines and when the first vine is reached raise the sixteen-foot lever upright, which will bring the hook close to the ground at the base of the vine. Make a quick hitch about the trunk of the vine as close to the ground as possible with a stout chain fastened to the hook, then with a long rope attach team to the upper end of the lever and pull.

The closer to the ground the chain is placed the less danger of breaking off of vine. But where a vine is broken off a little digging will allow of a second attachment of the chain and the vine can be removed. We have seen two men and a team with this appliance walk across a large field, removing every vine in the row in an incredibly short time.

The time of year is immaterial, save that cleaner work will be done in winter after rains soften the ground. There will also be less breakage then. If any part of the old trunk is left it will sucker for many years.

QUESTIONABLE METHODS.

The Cultivator has letters from certain Pomona subscribers, calling attention to an article published in the Pomona Review, written by B. A. Gilmore, representative of the Citrus Union at that place. The writers in all cases call attention to the following words:

"The California Cultivator has charged many times, without contradiction, that the method of arriving at the Exchange cost of packing is absolutely dishonest. The incident cited is that the Claremont Citrus Union last year shipped hundreds of sacks of oranges to Los Angeles. The sacks were returned, and the cost per sack for labor was about two cents. In figuring the cost of packing, their sacks were counted as boxes, and as the cost of these sacks was two cents and of packing around thirty cents, it was easy by this method to reduce the average cost of packing.

Now, when the returns for the fruit in these sacks were figured (these sacks had been reckoned boxes to reduce the cost of packing) it would be supposed that they would be reckoned the same to reduce the average net returns on a packed box of fruit. But not so, the money received in this case was not paid the grower direct, but used to raise the returns on other grades. The Cultivator claims this is one of the numerous methods of Exchange jugglery to deceive the grower."

The first and last quotations in that statement are both most surprising to the Cultivator. If. Mr. Gilmore will inform us in which issues we have so "many times without contradiction" charged "absolute" or any other kind of dishonesty, or wherein we have said there has been exercised "Exchange jugglery to deceive the grower," we will appreciate it and will publish such information for the benefit of others.

One subscriber inquiring as to where he can see the references above referred to says:

"The writer has been a constant subscriber of your paper, and reader of same, very closely, for about three years, and if you have ever published anything of the kind, as Mr. Gilmore states, it has escaped the writer's notice; which is strange if you have made such publications "many times."

Pomona seems to be the principal battleground this year of the war against the Exchange. If the fruit shippers not members of the Exchange have a better method of fruit marketing than that in force in the Exchange management, that should be sufficient to win friends for that system and make unnecessary claims which are untrue.

GUM DISEASE.

Editor of Cultivator: Kindly give cause and remedy for gum disease of orange trees. Is it contagious?—Subscriber, Covina.

The discussion of the cause of gum disease would lead into contention with many who have studied this subject for years. There is difference of opinion as to what the cause may be for it appears under varying conditions and in various locations. In general, however, it is considered well to keep from moistening ground near the trunk of the tree. Many treatments have been given in the Cultivator. One of the simplest treatments is to scrape off the scaling and diseased bark, also all diseased and gummy wood. Save and burn the scrapings to prevent spread of the disease, as it is contagious. Wash the cleaned parts with carbolic acid and water, equal parts. Smear over with tar.

EVERY crop takes plant-food from the soil that nature, unaided, cannot restore. The liberal use of a complete fertilizer, rich in POTASH, will revive old and worn out land to fertility, and insure larger crops from even the best of land.

Our books are free to farmers—they are not advertising pamphlets, but works of reference and a valuable addition to the farmer's library. They are free to all who will write for them.

DAME HISTORY'S PRIZE.

Dame History, teaching the nations in her school
The A B C of government—oh! long and hard the rule!—
Tapped sharply with her pencil; "Attention, class," she cries;
"Here comes the clay for modeling; now who will win the prize?
Let each of you, as best you may, a hero make and bring,
A leader and a statesman, a conqueror and king!"
Then all the little nations went eagerly to work,
Not one would fret or dawdle, not one was found to shirk,
And when the hour was ended, each hopeful nation brought
The product of her artistry, the Hero she had wrought.
Then Egypt came with Rameses, calm, stern and merciful;
Judah with warrior David, the poet beautiful;
And Persia brought Darius, the pattern of a king;
And three lovely Grecian sisters their work together bring;
Athens had noble Pericles, few greater men may see;
And Sparta brought Leonidas, slain at Thermopylae;
And the youngest, Alexander, whom men have named the Great;
Then Carthage came with Hannibal, trusted and loved too late;
Imperial Rome brought Caesar, the mightiest man of men—
The Nations paused and wondered a little space, and then
Up came the hurrying moderns, statues in either hand,
For Spain bore Isabella, and with her, Ferdinand;
And France her best-loved Henry, and great Napeoleon;
And Germany her Frederick', and Bismarck, Empire-son;
And Sweden with her conquering Charles; and Scotland with the Bruce;
And England came with armfuls, as doubtful whom to choose;
Queen Bess was there, and Cromwell, Nelson and Wellington,
And many a warlike monarch, and many a mighty son.

The Dame looked on exulting, with eyes of loving pride;
"Well done, my little Nations! Well done!" again she cried,
"Oh! wonderful and noble the statues you have wrought;
But now to give the prize, indeed, is harder than I thought;
For not a hero in the list, tho strangely great and fine,
But has some grievous blemish, some fault we all divine.
Oh! is there not a man of all these rulers great and true,
Quite sound and good and selfless, and noble through and through?"

Then timidly and shyly came the youngest from her seat;
"She's nothing but a baby; of course she can't compete;"
And yet she brought her statues—the dame looked on amazed;
She looked, she gazed, the started; her eyes with triumph blazed;
"Columbia, my darling, the prize you well have won,
Two rulers great without a flaw, Lincoln and Washington!"
—Samantha Whipple Shoup, Dubuque, Iowa.

Alimony is not a debt of honor, for a debt of honor is one which can not be collected by law. It's a debt of disgrace, and must be paid.—Sioux City Tribune.

The Strike at Nixon's

Lavina Nixon stopped working to sigh in a woe-begone fashion alien to her years.

O dear suz I wish I were Cinderella! I'm tired to death with this humdrum, do-nothing-but-work life. I hate it!"

"Why, Viny Nixon! What's on your mind to make you talk that way? I'm s'prised!" and Mrs. Nixon looked at her daughter compassionately.

"I can't help it; it's so. I just hate it! We're so different from everybody else. We never go anywhere nor have anything like other folks. Pa don't care any more for you'n me 'n he does for the rest of the machinery in the farm!"

Mrs. Nixon sank on a cracker box and pushed back her sunbonnet.

"Viny! Viny! How desperate you talk! Be you crazy?"

"No ma, I'm not crazy. I've been thinking, though, and I'm just getting to realize how we're being robbed. Pa buys us a few of the cheapest clothes to keep the neighbors from talking, just as he put up the lightnin' rods to save the barns being struck. He feeds us to keep us able to work, same as he oils the other tools to keep 'em from wearing out!"

"Oh, Viny!" gasped her mother, and the note of protest stung the girl.

"It's the awful truth," she persisted "If we was only his cook and hired girl we'd fare better'n we do now. We'd have wages and we could spend 'em where we liked. Now, we have next to nothing and get that charged to Furnam's one-horse store at the Bay. Besides, he scolds when the bill comes due in the fall—another thing we'd miss if we didn't belong to him."

Mrs. Nixon's loyal wifely heart longed to meet these accusations against the father with denial; but the truth in them was as a sword-thrust to her sensitive soul. That she could no longer hide his great defect of character from this child made her heart sick. She hid her face in her hands and a moan escaped her. Lavina mistook its meaning and spoke rapidly, that she might relieve her mind before her mother's patience should be exhausted.

"When the cattle don't do well he gives 'em change of feed; but we can live forever in the same place! When he got the harvester-and-binder did he ask if we needed a washing machine? Did the new seeder make him think we needed carpets or oilcloth to save our scrubbing bare floors? No. It isn't his back that bends for that! He takes a farm journal; but there isn't a woman's magazine to come to us! He pets the calves and old Shep; but I can't remember his kissing you in years! Can you?"

She paused for breath, her cheeks flushed and eyes flashing, so completely had this accusing spirit gained possession of her.

Mrs. Nixon shook her head as she wiped her eyes on a corner of her apron.

"'Tain't your pa's way to be demonstrative—I've got used to it—but he ain't all bad, Viny. He don't drink nor stay out nights and he ain't 's bossy 's some I've known; we can arrange the furniture's we want to and cook what we like; that's some comfort. We've went, too, quite a bit for us, this summer," she added.

"I should think we had. Five funerals and down to the Bay for Decoration—all those trips ended in the buryin' ground! And how'd we go? In the old democrat—I, holdin' an umbrella—while other folks was in top-buggies; you, in your old cashmere—ten years behind the times; me, wearin' my muslin with tight sleeves and ruffled skirt, beside the plain gores and leg-o-omutton's of the village girls." Lavina laughed hysterically at the comparison; but it held only bitter, ironical tones, which jarred and rasped and failed to soothe as a laugh should.

"Can't I put the ruffles on the sleeves and make 'em look—?"

"Like old frights!" interposed the girl. "No. I'll stay home till I get a new one; for I will have it."

Timid, yielding, Mrs. Nixon could bear no more and rose to go. Stopping beside Lavina, she wound her arms about her and kissed her passionately—with something of renunciation in the act—much as we kiss our dead. Viny the child, was lost; Viny, the discerning woman had spoken—had exposed her father's selfishness and rebelled against it. Silence had hitherto enshrouded this skeleton of the home life, but her words had made it impossible to hide it in even partial oblivion, again.

It was half-past 10. Since 9 o'clock Viny had stood beside the old-fashioned churn; still the butter refused to "come," Its very obstinacy seemed a part of the force which bound her to this hated life. Now, her resentment gave new strength to her tired arms and the rapid plunk-plunk-plunk of the dasher indicated her strong will.

Damp, cold and inconvenient, the milkroom fostered a revolutionary spirit. Its one small window opened toward the north. Sunshine might envelop the world, but it never crept in here with its softening, subduing, enriching power. In her present mood, this seemed another loss which taunted her. The racks were lined with time-worn pans; they must be cleaned and the milk taken out—the pigs were even now squealing lustily for it. So it was—work, work—work

At dinner, the sleazy cotton tablecloth, steel knives, and "ironstone china" grew hideous to her; the salt pork, potatoes and brown bread almost choked her with their coarseness; her father's sipping tea from his saucer seemed barbarous and the final scraping of the splint-bottomed chairs on the uneven floor made her shiver. She wished again to be Cinderella and thought of the prince as she glanced at the hired man.

Silent much of the afternoon, noting but her changing color revealed the thought-tempest raging within her. With the presumption of youth, before night she had decided to reform her father. When in the twilight she found him seated on an inverted pail, smoking and reading, leaning against the barn door, with less tact than decision, she dropped on a milking stool beside him. He looked at her curiously; the interruption annoyed him. Her request for money angered him. Her evident discontent aroused his instinct of self-preservation. With a laugh, misleading to her inexperience, he asked: "Where'd you get them ideas on women's rights?"

"In here," she answered, turning the newspaper on his knee and pointing to the "Woman's Column." Headed sometimes by fashions, at others by household recipes, it had looked inoffensive, and uninteresting to the farmer; he had not read it; his daughter devoured it. Glancing down the column his eye now caught a few isolated statements: "The wife should be a partner to the husband's business interests"—"Beautify and make the home pleasant"—"Give your wife an allowance"—"Dress well—" here he slammed the paper down vengefully, as though crushing it, crushed out of existence the disagreeable sentiment.

"Phm! domestic anarchy!" he grumbled; "don't let me hear any more of them fool notions—never. You won't get another muslin by my buyin' it—not this summer, one's enough at a time. You needn't get your ma to tease, either—'twon't make a bit of difference. And, mind, don't

Sievert Oil Burners

Superior to all others. A perfect system of heating with distillate oils. Non-explosive, safe, simple and economical. Made in sizes for Stoves, Ranges, Water Heaters, Furnaces and Boilers. Send for Circulars.

1007 N. ALAMEDA, LOS ANGELES

When writing advertisers mention Cultivator.

say any more 'bout goin' somewheres else to work; if you do, I'll collect your wages—yon ain't 18 yet, you know," and he left her abruptly.

"Pa Nixon" had not absorbed "reform" measures as Lavina had fancied he might. Too sanguine, defeat stunned her. She went back to the house thirsting for revenge, and sat by her window until long into the night planning how she might outwit him.

Days passed uneventfully save for much earnest, low-toned conversation between the girl and her mother. Tortured with indecision—whether to stand by the husband, or be swayed by the child—Mrs. Nixon felt they were facing a crisis; felt herself borne along, somewhat unwillingly, by the current which led to it.

Nothing more was seen of the "woman's column" in the weekly newspapers; the father clipped it out each week, prior to bringing it home. But Viny read it more eagerly still, at a neighbor's a half mile away.

Dame Nature had left the Nixon farm on the very top of Rocky Ledge as a housewife might hide away cake on the topmost pantry shelf. To reach it, one must climb a steep road choked with stones. Some swore at Jim Nixon, others at the pathmaster; a few, at stones in the abstract for this condition. Wide at the valley, it narrowed gradually; half up the ascent was a sharp bend called "Nixon's Elbow." Beyond was the cool shadow of the woods, the scent of brakes, moss, and blackberry bushes; then came the open sun-gilded acres.

That part of the land where the ledge sloped off toward the east, fell away with the rest, and the gnarled, old wind-racked trees, scattered here and there, were like monster pegs stuck in by a giant hand, to keep the whole from slipping down—down to where the river crept into the mainland and gave the place a name—"Nigger Nose" Bay.

Nixon crops were abundant; barns, numerous and large and their condition bespoke painstaking care. But the poor little house at the left seemed to be suffering the pains of vivisection from neglect and the elements. It might have held the Nixon pedigree for generations back, but looked orphaned in its impoverishment. Inside, the furnishings might have served frontier days without comment, but for the twentieth century they aroused suspicion. The blight of the master's sordidness branded the rooms; they were barren of coziness and home comforts.

He was a church member; but not a New Testament exponent. His Christianity had not submerged his selfishness or his will. It did make him honest, moral, humane to dumb things, a civil citizen and a grudging contributor to the Gospel. Here it ended.

The air was sweet with June roses as Mr. Nixon one day came from the field for dinner. The house was silent and tenantless. Windows were closed and the atmosphere stifling. The fire was out. A note which lay on the empty teakettle read: "Pa: We're down to Mrs. Blake's helping get up the sociable for the church. You'll have to churn; cream's in the cellar. We won't be home till late. Viny."

Why had they not asked him something about this? "You'll have to churn!" He did not quite like the situation—this being unable to refuse. "We're up against a cold dinner, Zed; the cooks have lit out," he remarked as the hired man came in.

"Good thing; good thing! it don't hurt a man to scare up game for himself once in awhile; he ain't so apt to cock his gun at the woman's cookin for a spell afterward," Zed answered.

"By crimus, Zed! Can you shack along without tea? The women folks hain't left a sliver to start a blaze with and time's limited," said Nixon, coming in directly with a plate of cold potatoes, a huge piece of dried beef, and a pie.

"Just like a camel crossin' Sahary! give me a starter on the town pump an' its all the same to me. I ain't no summer boarder."

A loaf of bread—with a newspaper under the edibles—a dipper of water convenient to both, and the menu was completed. Mr. Nixon murmured something about "furbelows beiu' missin'."

"'Nough said, 'nough said! it's more'n Eliger had!"

"You'll have to finish the cultivatin' alone; I've got to churn, y' see," throwing Viny's note to Zed. "The cream's sour's an old maid or I'd leave it; but it's churn it or loose it—one or t'other."

Zed was willing. His acceptance of the emergency put to shame the inner grumblings of his host. Lank-bodied, long-limbed, red-haired, good-natured, Zed One look into his face, with its mirth-bejeweled eyes and philanthropic smile, made him seem like an elongated sunbeam.

The clock struck 2 before the butter was down cellar smothered in cold water. When Mr. Nixon again came to the kitchen, it was to farther confusion. The chickens on the table flew out the window; those under neath dashed through the door.

"Drat them impudent hens; they've ruined them victuals!" But why should not the hens come in? Everything invitingly open, no screens to prevent and not a woman about to hollow "shoo." He dimly remembered Mrs. Nixon's having asked for a hen park in the spring.

Before 5 o'clock he was again at the house. Eggs to be gathered, pigs, calves and fowls to be fed, fire to build and pans to scald. All the women's work; it took his time! He also remembered again that his wife had asked for extra pans a few weeks since. He saw the reasonableness of her plea but did not acknowledge it.

His greeting at the breakfast table the next morning was cold and repelling. A warm dinner, however, made him fancy the old routine restored.

Afternoon found him in the potato field. At 4 o'clock a voice called over the fence: "Say, Nixon! where's your women folks?" It was Price, the produce merchant.

"Don't know," was the surly response as he dropped his hoe and the two went back to the house. On the table was another note; it said: "Pa: We are gone to Mrs. Merenus's birthday surprise. If Mr. Price should happen to come"—Oh, the irony of that word "happen!" he came regularly alternate Thursdays, and was due today—"the butter is worked and ready to mold. The steelyards and stamp hang on the end of the cupboard. Viny."

Mr. Price had customers who required butter in pound prints. Particular? Yes. But they paid extra. The buyer would accept it in no other form. Mr. Nixon was obliged to honor the demand. Why not? He claimed the proceeds of the sales? An hour later he started back to his work, resolved that this "gaddin' business should end."

His reproof that evening was quietly accepted and all went as usual for a few days.

Wednesday of the following week a third note informed him that Mrs. Nixon and Viny were at a Sunday school picnic. Under a napkin were left bits of pressed chicken, tarts and fruit cookies; also cake frosted and adorned with cinnamon drops.

(To be concluded.)

Cookery Recipes

RECIPES.

Dutch Scramble.—Put a good sized piece of butter in a saucepan, set it over the fire and when melted stir in a cupful of shredded codfish; allow the butter and fish to become well mixed, and if necessary add more butter; then break in five eggs and scramble. Season with pepper and salt and serve very hot.

* * *

Wax Beans.—An English recipe for serving wax beans is novel. Cut the bean breadthwise in half or quarter-inch pieces and boil in salted water. Drain well and prepare the following sauce: Make a sauce with equal quantities of flour and butter, add salt and pepper and a cupful of sour cream. Add the beans and allow them to boil up once, stirring all the time. If no sour cream is at hand sweet cream or rich sweet milk with a few drops of lemon juice will serve.

* * *

Lattice Potatoes.—Some sort of fried potatoes are relished with salad. If cut with a patent cutter that makes the pieces like a lattice they seem a little different from strips or shreds. Drop into cold water for half an hour, drain and dry on a cloth; then fry in deep, hot fat. Serve on a warm plate and dust with salt.

* * *

Mint Sauce.—Mint sauce is the customary addition to roast lamb. Chop the mint leaves fine and measure one-quarter cup. Add the same amount of sugar and one-half cup of vinegar. Set on the back part of the range and as soon as the sugar is dissolved and the vinegar is hot the sauce is ready for use. Cooking it spoils its best flavor.

* * *

Southern Mashed Potatoes.—Pare and boil eight large potatoes in salted water; mash, and season with one tablespoon of butter, one teaspoon of salt; one-half teaspoon of pepper and one-half cup of cream of milk. Beat thoroughly, and heap into a mould or buttered pie plate, topped with one teaspoon of butter. Place on the upper shelf of the oven and bake until the whole outside is a rich brown.

HOMELY HINTS.

A shoe case on each slothespress door is a help to order.

To sweep the attic, cellar or any very dusty floor, first dampen pieces of newspaper and throw around; they help collect the dust.

Keys that never stay in place may

be fastened to the knobs by small gilt cords.

Well ventilated bedrooms will prevent morning headaches and lassitude.

A cup of hot water drank before meals will relieve nausea and dyspepsia.

THE EXCHANGE UNDER A NEW NAME.

As will be noticed from the advertisement on the second page of the Cultivator, the Southern California Fruit Exchange will, after today, do business under the name of California Fruit Growers' Exchange. The reason for this change of name is stated to be that the exchange may have a broader field and not be considered sectional.

The Exchange holdings in Central and Northern California for the coming season will amount to over 50 per cent of the northern crop of citrus fruit, against less than 25 per cent in any other one year. At Highlands, the Exchange has an increase of some 200 to 300 cars and the same at East Highlands, with prospects also of some 200 to 300 cars additional at Corona.

During the past season, the Exchange has marketed 14,200 cars of oranges and lemons at an average price per car, net, f. o. b. California, every car included, of over $500, which is over $100 per car more than received for Exchange fruits during the previous year.

By the way, the advertisement above referred to will bear reading a second time and we would advise every citrus grower to do so.

* * *

A GOOD VETERINARY REMEDY.

The Paxton Veterinary Medical Co., who have an ad. in the Cultivator, recently received a letter from Donovan & Bourland, large liverymen in Los Angeles, in which they give a strong endorsement of the remedies put up by this company. Here is an extract from the letter: "We have used your cough and throat remedy; also your purgative pills in our stables for the last six months and find them the best veterinary remedies we have ever used."

* * *

Just issued, a beautifully illustrated, 80-page magazine, descriptive of farm life in Central California. Will mail you a copy free upon receipt of four cents in postage. Each article in this magazine is written by a practical farmer, fruit grower or dairyman. The illustrations are the best obtainable. This magazine tells the truth about California. If you are at all interested you should read it. Send four cents in postage to Editor Gateway Magazine, Chamber of Commerce, Stockton, California.

* * *

Attention is especially called to the adverstisement in this issue of Chesnutwood's Business Colleges at Fresno and Santa Cruz. Write for catalogue to either city and you will receive reliable information in regard to two excellent schools.

* * *

Orchardists will be interested in the advertisement in this issue of Rhodes Mfg. Co., of Grand Rapids, Mich. They have a good pruning shears.

* * *

The Rancho Verde Company, of Victorville, want 30 head of milk cows, either Jerseys or Guernseys. Read their ad. in the dairy department.

* * *

A good, second-hand gasoline engine is offered by the Gray, Lyon Co., of Riverside. Their ad. appears on our last page.

Los Angeles Markets.

Los Angeles, August 30, 1905.

Butter.

Butter market remains same as last week. At this time there is in cold storage 1,516,245 pounds of butter, as against 1,458,270 lbs. same date last year.

Store ....18 @23
Eastern, extra ....24 @25
Eastern, firsts .....21 @23
Eastern, seconds .....18 @20

Poultry.

There has been but slight change in the poultry situation, the quotations being firm, although the demand has been rather limited.

POULTRY—Old Roosters, per doz., $4.50@5; young Roosters, $5.50@7; Fryers, $3.50@4; Broilers, $2@3; Hens small, $4@5; large, $5.50@6.50; Live Turkeys, per lb., 19@22c; Spring Turkeys, 23@25c; Ducks, old, $4@4.50; young, $4@6; Geese, per pair, $1.75@2; Goslings, $2; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $1.50@$1.75.

Fresh Fruits.

Apples, per box, fancy, 85c@$1.15, common to choice, 40@75c; Crabapples, per small box, 60@75c; large, $1.40@1.75.

Figs—Per box, Black, 50@85c, as to size of package; White, 50@75c.

Pears—Per box, Bartlett, 75c@$1.50; bulk, per ton, nominal; other varieties, per box, 50c@$1.

Peaches—Per box, Mountain, 50@85c; carriers, 40@80c; open boxes, 60c@$1.50; bulk, per ton, $30@50.

Plums and Prunes.—Per small box or crate, 40c@$1, as to variety, open boxes, 65c@$1.25.

Quinces—Per box, 50@65c.

Grapes—Per box or crate, Seedless, 65@85c; Sweetwater, 40@65c; Muscats, 50@85c; Blacks, 50@85c; Tokays, 85c@$1; Isabella, $1; open boxes, 75c@$1.25, as to variety.

MELONS—Cantaloupes—Per crate, 75c@$1.25; Watermelons, per doz, $1@3; Nutmeg melons, 25@60c.

BERRIES—Blackberries—Per chest, $2@3.50.

Raspberries—Per chest, $6@9.

Strawberries—Per chest, Longworths, $6@8; large varieties, $4.50@6; Santa Clara, $8@10.

Huckleberries—Per lb., 5@7c.

Vegetables.

VEGETABLES—Tomatoes, per box, 50c@$1; Green Peppers, per box, Chile, 25@40c; do, Bell, 25@40c; Okra, per box, 40@60c; Beans, per lb., Green, 1@

1½c; do, Wax, 1½@2c; Lima, 4@6c; Garden Peas, per lb., 3@4c; Cucumbers, per box, 25@40c; Egg Plant, per box, 50@75c; Garlic, per lb., 5@5½c; Green Corn, per sk, 50c@$1.25; per crate, $1@1.25.

POTATOES—Per ctl.: River Burbanks, 50@70c; Salinas Burbanks, 90c @$1.15; Early Rose, nominal; Garnet Chile, 40@50c; Sweet Potatoes, $1.25 @$2.25.

ONIONS—Per sk, Yellow, 70@85c.

Dried Fruits.

Operations in the dried fruit market continue extensive. The undertone is one of marked strength at strong prices. Prunes have the call in all trade centers with dealers holding in anticipation of still higher prices. Apricots have practically been cleaned out of first hands. Peaches are firmly held. Raisins are well cleaned up and firm prices are predicted for the new crop. As no new quotations are available, we reprint those of last week.

DRIED FRUITS—Prices for carloan lots, f. o. b. at California common shipping points, in bags, are per lb, as follows:

Apples—Evaporated, 1905 crop, fancy, 7½c; choice, 6¾@7c; standard, 6¼@6½c; Sun Dried, nominal.

Peaches—Crawford, fancy, 8¾c; choice, 8@8¼c; standard, 7¾c; Muirs, fancy, 9¼c; choice, 8¼@8¾c; standard, 8c.

Prunes, 1905 crop—Sack basis, f. o. b., for boxed goods add ¼@½c; four-size basis, 3¼@3¾c; old crop, 2¾ @3c.

Apricots—Royal, fancy, 8¾@9c; choice, 7¼@8¼c; standard, 6¾@7c; Moorpark, fancy, 12c; choice, 8½@10c.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c, choice, 3¼c; standard, 2¾c; ungraded, 3½c.

Honey and Beeswax.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@ 6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 28@29c.

Hops.

The price of desirable old crop is nominal at 16@19c per lb., according to quality; new, 1905 crop, 14@15c.

Beans and Seeds.

BEANS—Prices per ctl. for sound selections; Large White, $2.75@2.90; small do. $3.50@3.75; Pea, $3.25; Limas, $5.50@5.75; Red, $6.50@8; Pink, fancy, $3.65@3.90; recleaned, ordinary to choice, $2@2.50; Bayos, $4@4.50; Blackeyes, $3.75@4.25; Red Kidneys, $4@4.50. Rain damaged lots of all descriptions offering from 50c@$2 a ctl. below foregoing figures, according to condition.

Live Stock.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4@4½c, gross weight; medium, 3½@4c; heavy 3½c, gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@3¾c, gross weight; Ewes, No. 1, 3@3¼c, gross weight.

LAMBS—Sucklings, $2.50@2.75 per head, or 4¼@4½c per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs, 5¾c; 130 to 275 lbs., 6c; 275 to 350 lbs., 5@ 5½c; rough heavy, 4¼@4½c; common, 3½@4c.

Hay and Feedstuffs.

HAY—Per ton: Wheat, $7.50@13.50; Wheat and Oat, $7@12.50; Oat, $6@ 11; Barley, $6@9; Clover, $7@10; Alfalfa, $6@9; Stock, $5@6.

New Crop—Wheat, $9@13.50; Oat, $7@11; Wheat and Oat, $7@12; Alfalfa, $6@9.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@ 24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $22.50@23.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

GROUND BARLEY—Per ton, $21.50 @22.50.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@28.50.

Flour and Cereals.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70 @4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.30@1.35; inferior grades, $1.15@ 1.30; White Milling, good to choice, $1.35@1.45 for new and higher for old.

BARLEY—Choice, No. 1 Feed, $1@ 1.05; some fancy up to $1.06¼; off grades, 97½@98¾c; Shipping and Brewing, $1.05@1.10; Chevalier, $1.10 @1.25.

OATS—Good to choice White, nominal; Red, $1.20@1.40 for new crop; Black, for seed, $1.40.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.40@1.45; small do, $1.55@1.62½; White, $1.37½ @1.42½; Eastern, Yellow, $1.40@ 1.42½; White, $1.40@1.42½; mixed, $1.40.

RYE—Good to choice, per ctl., nominal; new, $1.47½@1.50.

CITRUS MARKETS

The New York oranges markets for last week were about $1 per box lower than for several weeks preceding, but, notwithstanding the lower price, fruit was considered to have brought its full value. Offerings were quite heavy and several of the cars had probably been diverted from other points, as the fruit showed poorer than had been the rule for some time. California lemons brought high prices during the week, the great trouble being to secure supplies.

Sicily lemons were scarcer and will probably remain so for the next few weeks.

At Chicago, lemons have had a good steady demand. The market was firm and stock small. The orange supply was rather light and prices good. As the season is now rapidly growing to a close, all kinds of citrus fruits will undoubtedly bring good prices till the next season opens.

New York.

Sales of California fruit on Monday were six cars of oranges and one car of lemons and a car of grape fruit. Market ruled a little lower on nearly all grades on account of poorer fruit. Good qualities were about as high as last week. Lemons brought the same as last week, while grapefruit was a little lower, due to the fact that there was more offered than the market would take at the price at this season. Old Mission, fancy, brought $6.39 per box, average. A car of Independents, fancy ,from Highlands, brought $3.26 average per box. Stag, fancy, from the A. C. G. Exchange, Azusa, brought $5.10 average. In other brands, Pointer, choice, A. C. G. Exchange, averaged $4.16 per box, and Hunter, standard, from the same exchange brought $2.91 average.

Old Mission, fancy, grapefruit, from Fullerton, averaged $3.15, while the same fruit from the D-M Exchange, choice, brought $9 for the highest and averaged $8.95 per box. Lemons from W. S. Corwin, Highlands, brought $5.42 average, while Warrior, extra choice, from the Stewart Fruit Co., at Fernando, averaged $5.72.

On Tuesday the offerings were liberal, and no strictly fine fruit was offered. Five and a half cars of oranges and about one and a half cars of grapefruit were sold. It is expected that better prices will rule the balance of the week as some better grades of fruit are expected and the weather is favorable. Stag, fancy, Valencias, from the A. C. G. Exchange at Azusa, averaged $4.41 per box. Hunter, standard, from the same place, brought $3.31 per box. Our Monogram, from the C.C.U., Redlands, averaged $4.26. Ocean, extra fancy, Moffat Fruit Co., Rialto, averaged $4.04 per box. Some navels from the exchange at Glendora were Pointer, choice, with an average of $3.25. Grapefruit seemed to be considerably lower, the highest average was Rialto, fancy, C.C.U., which brought $3.15.

Wednesday's orange market recovered its old prices on four cars sold. A car of lemons from the Arlington Hts. Fruit Co. sold very high, the average being for fancys, $7.01, and extra choice, $5.66. Lemons are scarce, but oranges have been in over supply. Michigan peaches are coming in plentifully, which hurts the sale of fruit.

Boston.

On Monday the Citrus offerings of California fruit at the auction included four cars and one car of grapefruit. Late Valencias brought from $2.55 to $5.35; Jaffas, $3.25 to $5.30; grapefruit, $2.50 to $5.25.

Philadelphia.

Three cars were sold at this market Monday. aFncy Valencias brought $4.35; choice, $3.50; and standards, $2.75.

CITRUS SHIPMENTS.

The total citrus shipments for the season have been 28,906, of which 2845 were lemons.

Green Fruit.

The shipments to eastern points by the California Fruit Distributors continue heavy. Last Saturday seventy-one carloads were consigned to eastern cities. Boston and St. Paul held special sales Saturday to take care of the fruit. At Boston a car from Red Bluff brought gross $1214, although part of the fruit was over-ripe, while at St. Paul a car from Vacaville grossed $1139, and a car from Santa Clara grossed $1107. Both cars had considerable overripe and decayed fruit.

It is always easy to rejoice in afflictions if someone else has them.

CARROTS FOR THE TABLE.

In Country Gentleman I find the following timely paragraph: "There are not many people in this country who get as much good out of carrots as they ought to. This is not a popular vegetable for table use in America, the chief reason being that the roots are always allowed to grow too long. They become large, woody and strong. In Germany, where carrots are much more used, the small varieties, like Scarlet Forcing, are usually grown, and these are boiled and eaten when they have not reached more than half size. They are usually boiled until they are tender, and then served with cream sauce, or else they are baked in the dish with a roast of beef. Good, tender, halfgrown carrots served in this way are delicious. This vegetable ought to be popularized in America." I wish to emphatically endorse every word of this. Although I spent nearly a quarter of a century of my life in Germany, however, I never knew how good a dish of carrots can be until we had the half-grown roots cooked and served with cream sauce. Young carrots are also excellent to serve boiled with green peas. Any of our standard varieties of scarlet carrots will do so long as they are used while young and tender. We have to sow seed repeatedly during spring and summer in order to have a succession of half-grown roots, but it is well worth while to take pains to have them thus during the entire season.—Farm and Fireside.

IN WOMAN'S BREAST

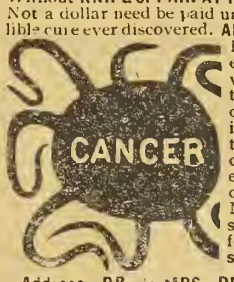
ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

THREE PHYSICIANS OFFER $1000

If They Fail to Cure Any Cancer

Without KNIFE or PAIN AT HALF PRICE for 30 days. Not a dollar need be paid until cured. Only infallible cure ever discovered. ABSOLUTE GUARANTEE.



Best book on cancers ever printed, Sent FREE with testimonials of thousands cured without a failure. A Pacific island plant makes the cures. Most wonderful discovery on earth. Small cancers cured at your home. No X-Ray or other swindle. Write today for our 130-page book, sent free.

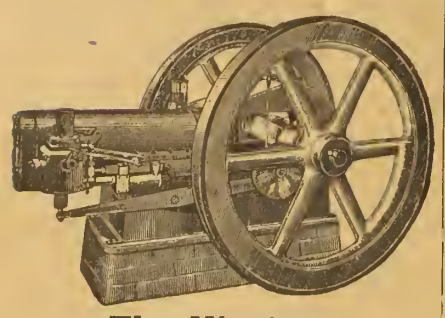
From Los Angeles Times, Wednesday, August 16, 1905:



The Western Gas Engine

LOCAL FIRM GETS PLUM.

Western Gas Engine Co Given Contract for Motor Machinery at Yuma Dam.

Complimentary to Los Angeles and Southern California, as recognized factors in the manufacturing field, the New York Engineering Company, which has the $800,000 contract for constructing the government's reclamation project above Yuma, has determined to use gas instead of steam in the immense work of water excavation at the Yuma damsite, and has ordered nine Los Angeles-built engines for that purpose from the Western Gas Engine Company of this city.

The supervising engineer of the New York concern, C. G. Young, intended to utilize steam in this pump work, but during a recent visit in Los Angeles he was convinced by tests that the gas engines manufactured by the local firm named would be far more advantageous than steam engines, both in power and economy. This recognition by New York of Southern California's machinery-manufacturing ability is keenly appreciated here.

NOTE.—The above news item chronicles the greatest victory every achieved by a California manufactured product. When the most famous expert engineers of this country, and in fact in the world, declare the Western to be the most reliable, substantial and economical power for this most important work, in preference to all other gas engines, East or West, and even in preference to steam, it puts a certain value upon the Western Gas and Distillate Engine that should make it the exclusive choice of every user of power. Numerous other gas engines recognized in this market and known to these engineers, were not even considered, on account of their known unreliability.

Much of the work will be done with steam, as we were unable to furnish within the time specified all of the engines wanted, but these nine, most of them of large size, will all be delivered within 30 days from the receipt of the order. These engines will be run with California No. 2 distillate.

E. POLYANTHEMA.

E. CALOPHYLLA.

The above cuts show the appearance of flowers and seed capsules of two valuable varieties of the Eucalyptus. They both grow hard, close grained wood and are most valuable for general uses. The importance of the Eucalypts as producers of oils, timber, fuel, ornamental uses, reclamation of waste places, sanitary effects, together with the fact that they are the most rapid growing trees in the world, cannot be overestimated.
